PyMuPDF Documentation

Release 1.18.8

Jorj X. McKie

Feb 06, 2021
## Contents

1 Introduction ................................................. 1
   1.1 Note on the Name fitz ................................. 2
   1.2 License ............................................. 2
   1.3 Covered Version ..................................... 2

2 Installation ................................................. 3
   2.1 Option 1: Install from Sources ....................... 3
      2.1.1 Step 1: Download PyMuPDF ....................... 3
      2.1.2 Step 2: Download and Generate MuPDF .......... 3
      2.1.3 Step 3: Build / Setup PyMuPDF .................. 4
   2.2 Option 2: Install from Binaries ....................... 4

3 Tutorial .................................................. 7
   3.1 Importing the Bindings ............................... 7
   3.2 Opening a Document ................................... 7
   3.3 Some Document Methods and Attributes ............... 8
   3.4 Accessing Meta Data .................................. 8
   3.5 Working with Outlines ................................ 8
   3.6 Working with Pages .................................... 9
      3.6.1 Inspecting the Links, Annotations or Form Fields of a Page 9
      3.6.2 Rendering a Page ................................ 10
      3.6.3 Saving the Page Image in a File .................. 10
      3.6.4 Displaying the Image in GUIs ..................... 10
         3.6.4.1 wxPython .................................... 10
         3.6.4.2 Tkinter ....................................... 11
         3.6.4.3 PyQt4, PyQt5, PySide ......................... 11
      3.6.5 Extracting Text and Images ....................... 11
      3.6.6 Searching for Text ................................ 12
   3.7 PDF Maintenance ...................................... 12
      3.7.1 Modifying, Creating, Re-arranging and Deleting Pages 13
      3.7.2 Joining and Splitting PDF Documents .............. 13
      3.7.3 Embedding Data .................................. 13
      3.7.4 Saving .......................................... 14
   3.8 Closing ............................................... 14
   3.9 Further Reading ....................................... 14

4 Collection of Recipes .................................... 15
4.1 Images
  4.1.1 How to Make Images from Document Pages
  4.1.2 How to Increase Image Resolution
  4.1.3 How to Create Partial Pixmaps (Clips)
  4.1.4 How to Create or Suppress Annotation Images
  4.1.5 How to Extract Images: Non-PDF Documents
  4.1.6 How to Extract Images: PDF Documents
  4.1.7 How to Handle Stencil Masks
  4.1.8 How to Make one PDF of all your Pictures (or Files)
  4.1.9 How to Create Vector Images
  4.1.10 How to Convert Images
  4.1.11 How to Use Pixmaps: Gluing Images
  4.1.12 How to Use Pixmaps: Making a Fractal
  4.1.13 How to Interface with NumPy
  4.1.14 How to Add Images to a PDF Page

4.2 Text
  4.2.1 How to Extract all Document Text
  4.2.2 How to Extract Text from within a Rectangle
  4.2.3 How to Extract Text in Natural Reading Order
  4.2.4 How to Extract Tables from Documents
  4.2.5 How to Mark Extracted Text
  4.2.6 How to Mark Searched Text
  4.2.7 How to Mark Non-horizontal Text
  4.2.8 How to Analyze Font Characteristics
  4.2.9 How to Insert Text
    4.2.9.1 How to Write Text Lines
    4.2.9.2 How to Fill a Text Box
    4.2.9.3 How to Use Non-Standard Encoding
  4.2.10 How to Extract Text from PDF

4.3 Annotations
  4.3.1 How to Add and Modify Annotations
  4.3.2 How to Use FreeText
  4.3.3 Using Buttons and JavaScript
  4.3.4 How to Use Ink Annotations

4.4 Drawing and Graphics

4.5 Extracting Drawings

4.6 Multiprocessing

4.7 General
  4.7.1 How to Open with a Wrong File Extension
  4.7.2 How to Embed or Attach Files
  4.7.3 How to Delete and Re-Arrange Pages
  4.7.4 How to Join PDFs
  4.7.5 How to Add Pages
  4.7.6 How To Dynamically Clean Up Corrupt PDFs
  4.7.7 How to Split Single Pages
  4.7.8 How to Combine Single Pages
  4.7.9 How to Convert Any Document to PDF
  4.7.10 How to Deal with Messages Issued by MuPDF
  4.7.11 How to Deal with PDF Encryption

4.8 Common Issues and their Solutions
  4.8.1 Changing Annotations: Unexpected Behaviour
    4.8.1.1 Problem
    4.8.1.2 Cause
    4.8.1.3 Solutions
  4.8.2 Misplaced Item Insertions on PDF Pages

Index ................................................................. 335
PyMuPDF is a Python binding for MuPDF – “a lightweight PDF and XPS viewer”.

MuPDF can access files in PDF, XPS, OpenXPS, CBZ (comic book archive), FB2 and EPUB (e-book) formats. These are files with extensions .pdf, .xps, .oxps, .cbz, .fb2 or .epub (so you can develop e-book viewers in Python …).

PyMuPDF provides access to many important functions of MuPDF from within a Python environment, and we are continuously seeking to expand this function set.

MuPDF stands out among all similar products for its top rendering capability and unsurpassed processing speed. At the same time, its “light weight” makes it an excellent choice for platforms where resources are typically limited, like smartphones.

Check this out yourself and compare the various free PDF-viewers. In terms of speed and rendering quality SumatraPDF ranges at the top (apart from MuPDF’s own standalone viewer) – since it has changed its library basis to MuPDF!

While PyMuPDF has been available since several years for an earlier version of MuPDF (v1.2, called fitz-python then), it was until only mid May 2015, that its creator and a few co-workers decided to elevate it to support current releases of MuPDF.

PyMuPDF runs and has been tested on Mac, Linux, Windows XP SP2 and up, Python 2.7 through Python 3.7 (note that Python supports Windows XP only up to v3.4), 32bit and 64bit versions. Other platforms should work too, as long as MuPDF and Python support them.

PyMuPDF is hosted on GitHub. We also are registered on PyPI.
For MS Windows and popular Python versions on Mac OSX and Linux we have created wheels. So installation should be convenient enough for hopefully most of our users: just issue

```bash
pip install --upgrade pymupdf
```

If your platform is not among those supported with a wheel, your installation consists of two separate steps:

1. Installation of MuPDF: this involves downloading the source from their website and then compiling it on your machine. Adjust `setup.py` to point to the right directories (next step), before you try generating PyMuPDF.

2. Installation of PyMuPDF: this step is normal Python procedure. Usually you will have to adapt the `setup.py` to point to correct `include` and `lib` directories of your generated MuPDF.

For installation details check out the respective chapter.

There exist several demo and example programs in the main repository, ranging from simple code snippets to full-featured utilities, like text extraction, PDF joiners and bookmark maintenance.

Interesting PDF manipulation and generation functions have been added over time, including metadata and bookmark maintenance, document restructuring, annotation / link handling and document or page creation.

### 1.1 Note on the Name `fitz`

The standard Python import statement for this library is `import fitz`. This has a historical reason:

The original rendering library for MuPDF was called `Libart`.

“After Artifex Software acquired the MuPDF project, the development focus shifted on writing a new modern graphics library called *Fitz*. Fitz was originally intended as an R&D project to replace the aging Ghostscript graphics library, but has instead become the rendering engine powering MuPDF.”* (Quoted from [Wikipedia](https://en.wikipedia.org/wiki/MuPDF)).

### 1.2 License

PyMuPDF is distributed under GNU GPL V3 (or later, at your choice).

MuPDF is distributed under a separate license, the GNU AFFERO GPL V3.

Both licenses apply, when you use PyMuPDF.

**Note:** Version 3 of the GNU AFFERO GPL is a lot less restrictive than its earlier versions used to be. It basically is an open source freeware license, that obliges your software to also being open source and freeware. Consult [this website](https://www.gnu.org/licenses/agpl-3.0.en.html), if you want to create a commercial product with PyMuPDF.

### 1.3 Covered Version

This documentation covers PyMuPDF v1.18.8 features as of **2021-02-03 19:56:11**.

**Note:** The major and minor versions of PyMuPDF and MuPDF will always be the same. Only the third qualifier (patch level) may deviate from that of MuPDF.
PyMuPDF can be installed from sources as follows or from wheels, see *Option 2: Install from Binaries.*

## 2.1 Option 1: Install from Sources

This is a three-step process.

### 2.1.1 Step 1: Download PyMuPDF

Download the sources from https://pypi.org/project/PyMuPDF/#files and decompress them.

### 2.1.2 Step 2: Download and Generate MuPDF

Download `mupdf-x.xx.x-source.tar.gz` from Mupdf and unzip / decompress it. Make sure to download the (sub-) version for which PyMuPDF has stated its compatibility.

**Note:** The latest MuPDF development sources are available on https://github.com/ArtifexSoftware/mupdf – this is not what you want here.

### Applying any Changes and Hot Fixes to MuPDF Sources

On occasion, vital hot fixes or functional enhancements must be applied to MuPDF sources before it is generated.

Any such files are contained in the `fitz` directory of the PyMuPDF homepage – their names all start with an underscore “_”. Currently (v1.16.x), these files and their copy destinations are the following:

- `_config.h` – (Optional) PyMuPDF’s configuration to control the binary file size. Copy-rename it to `/include/mupdf/fitz/config.h`. This reduces the size of the PyMuPDF binary extension module to around 11 MB. If omitting this change, that size will be over 30 MB – without impacting functionality.
Generate MuPDF

The MuPDF source includes generation procedures / makefiles for numerous platforms. For Windows platforms, Visual Studio solution and project definitions are provided.

PyMuPDF’s homepage contains additional details and hints.

2.1.3 Step 3: Build / Setup PyMuPDF

Adjust the setup.py script as necessary. E.g. make sure that:

- the include directories are correctly set in sync with your directory structure
- the object code libraries are correctly defined

Now perform a `python setup.py install`.

Note: You can also install from the sources of the Github repository. These do not contain the pre-generated files `fitz.py` or `fitz_wrap.c`, which instead are generated by the installation script `setup.py`. To use it, SWIG must be installed on your system.

2.2 Option 2: Install from Binaries

You can install PyMuPDF from Python wheels. The wheels are self-contained, i.e. you will not need any other software nor download / install MuPDF to run PyMuPDF scripts. This installation option is available for all MS Windows and the most popular 64-bit Mac OSX and Linux platforms for Python versions 3.6 through 3.9. Windows binaries are provided for Python 32-bit and 64-bit versions.

Note: For the time being, wheels for Python versions 2.7 and 3.5 are generated as well, but not uploaded to PyPI until explicitly requested via an issue. Starting year 2021, support for these wheel versions will be dropped entirely.

Overview of wheel names (PyMuPDF version is x.xx.xx):

<table>
<thead>
<tr>
<th>Wheel Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyMuPDF-x.xx.xx-cp36-cp36m-macosx_10_9_x86_64.whl</td>

</tr>
<tr>
<td>PyMuPDF-x.xx.xx-cp39-cp39-win32.whl</td>
</tr>
<tr>
<td>PyMuPDF-x.xx.xx-cp39-cp39-win_amd64.whl</td>
</tr>
</tbody>
</table>

Older versions can be found in the releases directory of our home page https://github.com/pymupdf/PyMuPDF/releases.
If you unexpectedly run into problems installing the wheel for your system, please make sure you have updated your PIP to the current version.
This tutorial will show you the use of PyMuPDF, MuPDF in Python, step by step.

Because MuPDF supports not only PDF, but also XPS, OpenXPS, CBZ, CBR, FB2 and EPUB formats, so does PyMuPDF. Nevertheless, for the sake of brevity we will only talk about PDF files. At places where indeed only PDF files are supported, this will be mentioned explicitly.

### 3.1 Importing the Bindings

The Python bindings to MuPDF are made available by this import statement. We also show here how your version can be checked:

```python
>>> import fitz

>>> print(fitz.__doc__)
PyMuPDF 1.16.0: Python bindings for the MuPDF 1.16.0 library.
Built for Python 3.7 on win32 (64-bit).
```

### 3.2 Opening a Document

To access a supported document, it must be opened with the following statement:

```python
doc = fitz.open(filename)  # or fitz.Document(filename)
```

This creates the `Document` object. `doc. filename` must be a Python string (or a pathlib.Path) specifying the name of an existing file.

It is also possible to open a document from memory data, or to create a new, empty PDF. See `Document` for details. You can also use `Document` as a context manager.

---

1 PyMuPDF lets you also open several image file types just like normal documents. See section Supported Input Image Formats in chapter Pixmap for more comments.
A document contains many attributes and functions. Among them are meta information (like “author” or “subject”), number of total pages, outline and encryption information.

### 3.3 Some Document Methods and Attributes

<table>
<thead>
<tr>
<th>Method / Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Document.page_count</code></td>
<td>the number of pages (int)</td>
</tr>
<tr>
<td><code>Document.metadata</code></td>
<td>the metadata (dict)</td>
</tr>
<tr>
<td><code>Document.get_toc()</code></td>
<td>get the table of contents (list)</td>
</tr>
<tr>
<td><code>Document.load_page()</code></td>
<td>read a Page</td>
</tr>
</tbody>
</table>

### 3.4 Accessing Meta Data

PyMuPDF fully supports standard metadata. `Document.metadata` is a Python dictionary with the following keys. It is available for all document types, though not all entries may always contain data. For details of their meanings and formats consult the respective manuals, e.g. Adobe PDF References for PDF. Further information can also be found in chapter `Document`. The meta data fields are strings or `None` if not otherwise indicated. Also be aware that not all of them always contain meaningful data – even if they are not `None`.

<table>

**Note:** Apart from these standard metadata, PDF documents starting from PDF version 1.4 may also contain so-called “metadata streams” (see also stream). Information in such streams is coded in XML. PyMuPDF deliberately contains no XML components, so we do not directly support access to information contained therein. But you can extract the stream as a whole, inspect or modify it using a package like lxml and then store the result back into the PDF. If you want, you can also delete these data altogether.

**Note:** There are two utility scripts in the repository that import (PDF only) resp. export metadata from resp. to CSV files.

### 3.5 Working with Outlines

The easiest way to get all outlines (also called “bookmarks”) of a document, is by loading its table of contents:
toc = doc.get_toc()

This will return a Python list of lists \[[ lvl, title, page, \ldots, \ldots]\] which looks much like a conventional table of contents found in books.

\( lvl \) is the hierarchy level of the entry (starting from 1), \( title \) is the entry’s title, and \( page \) the page number (1-based!). Other parameters describe details of the bookmark target.

**Note:** There are two utility scripts in the repository that import (PDF only) resp. export table of contents from resp. to CSV files.

### 3.6 Working with Pages

*Page* handling is at the core of MuPDF’s functionality.

- You can render a page into a raster or vector (SVG) image, optionally zooming, rotating, shifting or shearing it.
- You can extract a page’s text and images in many formats and search for text strings.
- For PDF documents many more methods are available to add text or images to pages.

First, a *Page* must be created. This is a method of *Document*:

```python
code
page = doc.load_page(pno)  # loads page number 'pno' of the document (0-based)
page = doc[pno]  # the short form
```

Any integer \(-\infty < pno < page_count\) is possible here. Negative numbers count backwards from the end, so \(doc[-1]\) is the last page, like with Python sequences.

Some more advanced way would be using the document as an *iterator* over its pages:

```python
for page in doc:
    # do something with 'page'

# ... or read backwards
for page in reversed(doc):
    # do something with 'page'

# ... or even use 'slicing'
for page in doc.pages(start, stop, step):
    # do something with 'page'
```

Once you have your page, here is what you would typically do with it:

#### 3.6.1 Inspecting the Links, Annotations or Form Fields of a Page

Links are shown as “hot areas” when a document is displayed with some viewer software. If you click while your cursor shows a hand symbol, you will usually be taken to the taget that is encoded in that hot area. Here is how to get all links:

```python
# get all links on a page
links = page.get_links()
```
links is a Python list of dictionaries. For details see Page.getLinks().

You can also use an iterator which emits one link at a time:

```python
for link in page.links():
    # do something with 'link'
```

If dealing with a PDF document page, there may also exist annotations (Annot) or form fields (Widget), each of which have their own iterators:

```python
for annot in page.annots():
    # do something with 'annot'
for field in page.widgets():
    # do something with 'field'
```

### 3.6.2 Rendering a Page

This example creates a raster image of a page’s content:

```python
pix = page.get_pixmap()
```

pix is a Pixmap object which (in this case) contains an RGB image of the page, ready to be used for many purposes. Method Page.get_pixmap() offers lots of variations for controlling the image: resolution, colorspace (e.g. to produce a grayscale image or an image with a subtractive color scheme), transparency, rotation, mirroring, shifting, shearing, etc. For example: to create an RGBA image (i.e. containing an alpha channel), specify `pix = page.get_pixmap(alpha=True)`.

A Pixmap contains a number of methods and attributes which are referenced below. Among them are the integers width, height (each in pixels) and stride (number of bytes of one horizontal image line). Attribute samples represents a rectangular area of bytes representing the image data (a Python bytes object).

**Note:** You can also create a vector image of a page by using Page.getSVGimage(). Refer to this Wiki for details.

### 3.6.3 Saving the Page Image in a File

We can simply store the image in a PNG file:

```python
pix.writeImage("page-%i.png" % page.number)
```

### 3.6.4 Displaying the Image in GUIs

We can also use it in GUI dialog managers. Pixmap.samples represents an area of bytes of all the pixels as a Python bytes object. Here are some examples, find more in the examples directory.

#### 3.6.4.1 wxPython

Consult their documentation for adjustments to RGB(A) pixmaps and, potentially, specifics for your wxPython release:
If `pix.alpha`:
   `bitmap = wx.Bitmap.FromBufferRGBA(pix.width, pix.height, pix.samples)`
else:
   `bitmap = wx.Bitmap.FromBuffer(pix.width, pix.height, pix.samples)`

### 3.6.4.2 Tkinter

Please also see section 3.19 of the Pillow documentation:

```python
from PIL import Image, ImageTk

# set the mode depending on alpha
mode = "RGBA" if pix.alpha else "RGB"
img = Image.frombytes(mode, [pix.width, pix.height], pix.samples)
tkimg = ImageTk.PhotoImage(img)
```

The following avoids using Pillow:

```python
# remove alpha if present
pix1 = fitz.Pixmap(pix, 0) if pix.alpha else pix  # PPM does not support transparency
imgdata = pix1.getImageData("ppm")  # extremely fast!
tkimg = tkinter.PhotoImage(data = imgdata)
```

If you are looking for a complete Tkinter script paging through any supported document, here it is! It can also zoom into pages, and it runs under Python 2 or 3. It requires the extremely handy PySimpleGUI pure Python package.

### 3.6.4.3 PyQt4, PyQt5, PySide

Please also see section 3.16 of the Pillow documentation:

```python
from PIL import Image, ImageQt

# set the mode depending on alpha
mode = "RGBA" if pix.alpha else "RGB"
img = Image.frombytes(mode, [pix.width, pix.height], pix.samples)
qtimg = ImageQt.ImageQt(img)
```

Again, you also can get along without using PIL if you use the pixmap `stride` property:

```python
from PyQt<x>.QtGui import QImage

# set the correct QImage format depending on alpha
fmt = QImage.Format_RGBA8888 if pix.alpha else QImage.Format_RGB8888
qtimg = QImage(pix.samples, pix.width, pix.height, pix.stride, fmt)
```

### 3.6.5 Extracting Text and Images

We can also extract all text, images and other information of a page in many different forms, and levels of detail:

```python
text = page.get_text(opt)
```
Use one of the following strings for `opt` to obtain different formats:

- “text”: (default) plain text with line breaks. No formatting, no text position details, no images.
- “blocks”: generate a list of text blocks (= paragraphs).
- “words”: generate a list of words (strings not containing spaces).
- “html”: creates a full visual version of the page including any images. This can be displayed with your internet browser.
- “dict” / “json”: same information level as HTML, but provided as a Python dictionary or resp. JSON string. See `TextPage.extractDICT()` resp. `TextPage.extractJSON()` for details of its structure.
- “xhtml”: text information level as the TEXT version but includes images. Can also be displayed by internet browsers.
- “xml”: contains no images, but full position and font information down to each single text character. Use an XML module to interpret.

To give you an idea about the output of these alternatives, we did text example extracts. See Appendix 2: Details on Text Extraction.

### 3.6.6 Searching for Text

You can find out, exactly where on a page a certain text string appears:

```python
areas = page.search_for("mupdf")
```

This delivers a list of rectangles (see `Rect`), each of which surrounds one occurrence of the string “mupdf” (case insensitive). You could use this information to e.g. highlight those areas (PDF only) or create a cross reference of the document.

Please also do have a look at chapter Working together: DisplayList and TextPage and at demo programs demo.py and demo-lowlevel.py. Among other things they contain details on how the TextPage, Device and DisplayList classes can be used for a more direct control, e.g. when performance considerations suggest it.

### 3.7 PDF Maintenance

PDFs are the only document type that can be modified using PyMuPDF. Other file types are read-only.

However, you can convert any document (including images) to a PDF and then apply all PyMuPDF features to the conversion result. Find out more here `Document.convert_to_pdf()` and also look at the demo script pdf-converter.py which can convert any supported document to PDF.

`Document.save()` always stores a PDF in its current (potentially modified) state on disk.

You normally can choose whether to save to a new file, or just append your modifications to the existing one (“incremental save”), which often is very much faster.

The following describes ways how you can manipulate PDF documents. This description is by no means complete: much more can be found in the following chapters.

---

2 `Page.get_text()` is a convenience wrapper for several methods of another PyMuPDF class, TextPage. The names of these methods correspond to the argument string passed to `Page.get_text()`: `Page.get_text("dict")` is equivalent to `TextPage.extractDICT()`.
3.7.1 Modifying, Creating, Re-arranging and Deleting Pages

There are several ways to manipulate the so-called page tree (a structure describing all the pages) of a PDF:

- \( \text{Document.delete_page()} \) and \( \text{Document.delete_pages()} \) delete pages.
- \( \text{Document.copyPage()}, \text{Document.fullcopyPage()} \) and \( \text{Document.movePage()} \) copy or move a page to other locations within the same document.
- \( \text{Document.select()} \) shrinks a PDF down to selected pages. Parameter is a sequence\(^3\) of the page numbers that you want to keep. These integers must all be in range \( 0 \leq i < \text{page_count} \). When executed, all pages missing in this list will be deleted. Remaining pages will occur in the sequence and as many times (!) as you specify them.

So you can easily create new PDFs with

- the first or last 10 pages,
- only the odd or only the even pages (for doing double-sided printing),
- pages that do or don’t contain a given text,
- reverse the page sequence, …

… whatever you can think of.

The saved new document will contain links, annotations and bookmarks that are still valid (i.a.w. either pointing to a selected page or to some external resource).

- \( \text{Document.insert_page()} \) and \( \text{Document.new_page()} \) insert new pages.

Pages themselves can moreover be modified by a range of methods (e.g. page rotation, annotation and link maintenance, text and image insertion).

3.7.2 Joining and Splitting PDF Documents

Method \( \text{Document.insert_pdf()} \) copies pages between different PDF documents. Here is a simple joiner example (\( \text{doc1} \) and \( \text{doc2} \) being openend PDFs):

```python
# append complete doc2 to the end of doc1
doc1.insert_pdf(doc2)
```

Here is a snippet that splits \( \text{doc1} \). It creates a new document of its first and its last 10 pages:

```python
doc2 = fitz.open()  # new empty PDF
doc2.insert_pdf(doc1, to_page = 9)  # first 10 pages
doc2.insert_pdf(doc1, from_page = len(doc1) - 10)  # last 10 pages
doc2.save("first-and-last-10.pdf")
```

More can be found in the \text{Document} chapter. Also have a look at \text{PDFjoiner.py}.

3.7.3 Embedding Data

PDFs can be used as containers for arbitrary data (executables, other PDFs, text or binary files, etc.) much like ZIP archives.

\(^3\) “Sequences” are Python objects conforming to the sequence protocol. These objects implement a method named \( \text{__getitem__()} \). Best known examples are Python tuples and lists. But \text{array.array}, \text{numpy.array} and PyMuPDF’s “geometry” objects (\text{Operator Algebra for Geometry Objects}) are sequences, too. Refer to \text{Using Python Sequences as Arguments in PyMuPDF} for details.
PyMuPDF fully supports this feature via \texttt{Document embfile_*} methods and attributes. For some detail read \textit{Appendix 3: Considerations on Embedded Files}, consult the Wiki on embedding files, or the example scripts \texttt{embedded-copy.py}, \texttt{embedded-export.py}, \texttt{embedded-import.py}, and \texttt{embedded-list.py}.

### 3.7.4 Saving

As mentioned above, \texttt{Document.save()} will \textbf{always} save the document in its current state.

You can write changes back to the \textbf{original PDF} by specifying option \texttt{incremental=True}. This process is (usually) \textbf{extremely fast}, since changes are \textbf{appended to the original file} without completely rewriting it.

\texttt{Document.save()} options correspond to options of MuPDF’s command line utility \texttt{mutool clean}, see the following table.

<table>
<thead>
<tr>
<th>Save Option</th>
<th>mutool</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>garbage=1</td>
<td>g</td>
<td>garbage collect unused objects</td>
</tr>
<tr>
<td>garbage=2</td>
<td>gg</td>
<td>in addition to 1, compact \texttt{xref} tables</td>
</tr>
<tr>
<td>garbage=3</td>
<td>ggg</td>
<td>in addition to 2, merge duplicate objects</td>
</tr>
<tr>
<td>garbage=4</td>
<td>gggg</td>
<td>in addition to 3, merge duplicate stream content</td>
</tr>
<tr>
<td>clean=True</td>
<td>cs</td>
<td>clean and sanitize content streams</td>
</tr>
<tr>
<td>deflate=True</td>
<td>z</td>
<td>deflate uncompressed streams</td>
</tr>
<tr>
<td>deflate_images=True</td>
<td>i</td>
<td>deflate image streams</td>
</tr>
<tr>
<td>deflate_fonts=True</td>
<td>f</td>
<td>deflate fontfile streams</td>
</tr>
<tr>
<td>ascii=True</td>
<td>a</td>
<td>convert binary data to ASCII format</td>
</tr>
<tr>
<td>linear=True</td>
<td>l</td>
<td>create a linearized version</td>
</tr>
<tr>
<td>expand=True</td>
<td>d</td>
<td>decompress all streams</td>
</tr>
</tbody>
</table>

\textbf{Note:} For an explanation of terms like \textit{object, stream, xref} consult the \textit{Glossary} chapter.

For example, \texttt{mutool clean -ggggz file.pdf} yields excellent compression results. It corresponds to \texttt{doc.save(filename, garbage=4, deflate=True)}.

### 3.8 Closing

It is often desirable to “close” a document to relinquish control of the underlying file to the OS, while your program continues.

This can be achieved by the \texttt{Document.close()} method. Apart from closing the underlying file, buffer areas associated with the document will be freed.

### 3.9 Further Reading

Also have a look at PyMuPDF’s Wiki pages. Especially those named in the sidebar under title “\textbf{Recipes}” cover over 15 topics written in “How-To” style.

This document also contains a \textit{Collection of Recipes}. This chapter has close connection to the aforementioned recipes, and it will be extended with more content over time.
A collection of recipes in “How-To” format for using PyMuPDF. We aim to extend this section over time. Where appropriate we will refer to the corresponding Wiki pages, but some duplication may still occur.

### 4.1 Images

#### 4.1.1 How to Make Images from Document Pages

This little script will take a document filename and generate a PNG file from each of its pages.

The document can be any supported type like PDF, XPS, etc.

The script works as a command line tool which expects the filename being supplied as a parameter. The generated image files (1 per page) are stored in the directory of the script:

```python
import sys, fitz  # import the binding
fname = sys.argv[1]  # get filename from command line
doc = fitz.open(fname)  # open document
for page in doc:  # iterate through the pages
    pix = page.get_pixmap(alpha = False)  # render page to an image
    pix.writePNG("page-\$i.png" % page.number)  # store image as a PNG
```

The script directory will now contain PNG image files named `page-0.png`, `page-1.png`, etc. Pictures have the dimension of their pages, e.g. 595 x 842 pixels for an A4 portrait sized page. They will have a resolution of 72 dpi in x and y dimension and have no transparency. You can change all that – for how to do this, read the next sections.
4.1.2 How to Increase Image Resolution

The image of a document page is represented by a Pixmap, and the simplest way to create a pixmap is via method Page.get_pixmap().

This method has many options for influencing the result. The most important among them is the Matrix, which lets you zoom, rotate, distort or mirror the outcome.

Page.get_pixmap() by default will use the Identity matrix, which does nothing.

In the following, we apply a zoom factor of 2 to each dimension, which will generate an image with a four times better resolution for us (and also about 4 times the size):

```python
zoom_x = 2.0  # horizontal zoom
zoom_y = 2.0  # vertical zoom
mat = fitz.Matrix(zoom_x, zoom_y)  # zoom factor 2 in each dimension
pix = page.get_pixmap(matrix=mat)  # use 'mat' instead of the identity matrix
```

4.1.3 How to Create Partial Pixmaps (Clips)

You do not always need the full image of a page. This may be the case e.g. when you display the image in a GUI and would like to zoom into a part of the page.

Let’s assume your GUI window has room to display a full document page, but you now want to fill this room with the bottom right quarter of your page, thus using a four times better resolution.

To achieve this, we define a rectangle equal to the area we want to appear in the GUI and call it “clip”. One way of constructing rectangles in PyMuPDF is by providing two diagonally opposite corners, which is what we are doing here.

```python
mat = fitz.Matrix(2, 2)  # zoom factor 2 in each direction
rect = page.rect  # the page rectangle
mp = (rect.tl + rect.br) / 2  # its middle point, becomes top-left of clip
clip = fitz.Rect(mp, rect.br)  # the area we want
pix = page.get_pixmap(matrix=mat, clip=clip)
```

In the above we construct clip by specifying two diagonally opposite points: the middle point mp of the page rectangle, and its bottom right, rect.br.
4.1.4 How to Create or Suppress Annotation Images

Normally, the pixmap of a page also shows the page’s annotations. Occasionally, this may not be desirable. To suppress the annotation images on a rendered page, just specify `annots=False` in `Page.get_pixmap()`. You can also render annotations separately: `Annot` objects have their own `Annot.get_pixmap()` method. The resulting pixmap has the same dimensions as the annotation rectangle.

4.1.5 How to Extract Images: Non-PDF Documents

In contrast to the previous sections, this section deals with extracting images contained in documents, so they can be displayed as part of one or more pages.

If you want to recreate the original image in file form or as a memory area, you have basically two options:

1. Convert your document to a PDF, and then use one of the PDF-only extraction methods. This snippet will convert a document to PDF:

```python
>>> pdfbytes = doc.convert_to_pdf()  # this a bytes object
>>> pdf = fitz.open("pdf", pdfbytes)  # open it as a PDF document
>>> # now use 'pdf' like any PDF document
```

2. Use `Page.get_text()` with the “dict” parameter. This will extract all text and images shown on the page, formatted as a Python dictionary. Every image will occur in an image block, containing meta information and the binary image data. For details of the dictionary’s structure, see `TextPage`. The method works equally well for PDF files. This creates a list of all images shown on a page:

```python
>>> d = page.get_text("dict")
>>> blocks = d["blocks"]
>>> imgblocks = [b for b in blocks if b["type"] == 1]
```

Each item in “imgblocks” is a dictionary which looks like this:

```json
{"type": 1, "bbox": (x0, y0, x1, y1), "width": w, "height": h, "ext": "png", "image": ...}
```

4.1.6 How to Extract Images: PDF Documents

Like any other “object” in a PDF, images are identified by a cross reference number (`xref`, an integer). If you know this number, you have two ways to access the image’s data:

1. Create a `Pixmap` of the image with instruction `pix = fitz.Pixmap(doc, xref)`. This method is very fast (single digit micro-seconds). The pixmap’s properties (width, height, ...) will reflect the ones of the image. In this case there is no way to tell which image format the embedded original has.
2. **Extract** the image with \( \text{img} = \text{doc}.\text{extract}_\text{image}(\text{xref}) \). This is a dictionary containing the binary image data as \( \text{img}[\text{“image”}] \). A number of meta data are also provided – mostly the same as you would find in the pixmap of the image. The major difference is string \( \text{img}[\text{“ext”}] \), which specifies the image format: apart from “png”, strings like “jpeg”, “bmp”, “tiff”, etc. can also occur. Use this string as the file extension if you want to store to disk. The execution speed of this method should be compared to the combined speed of the statements \( \text{pix} = \text{fitz}.\text{Pixmap}(...); \text{pix.getPNGData()} \). If the embedded image is in PNG format, the speed of \( \text{Document}.\text{extract}_\text{image}() \) is about the same (and the binary image data are identical). Otherwise, this method is thousands of times faster, and the image data is much smaller.

The question remains: **“How do I know those ‘xref’ numbers of images?”**. There are two answers to this:

a. **“Inspect the page objects:”** Loop through the items of \( \text{Page}.\text{get_images}() \). It is a list of list, and its items look like \([\text{xref}, \text{smask}, \ldots] \), containing the \( \text{xref} \) of an image. This \( \text{xref} \) can then be used with one of the above methods. Use this method for **valid (undamaged)** documents. Be wary however, that the same image may be referenced multiple times (by different pages), so you might want to provide a mechanism avoiding multiple extracts.

b. **“No need to know:”** Loop through the list of all \( \text{xrefs} \) of the document and perform a \( \text{Document}.\text{extract}_\text{image}() \) for each one. If the returned dictionary is empty, then continue – this \( \text{xref} \) is no image. Use this method if the PDF is **damaged (unusable pages)**. Note that a PDF often contains “pseudo-images” (“stencil masks”) with the special purpose of defining the transparency of some other image. You may want to provide logic to exclude those from extraction. Also have a look at the next section.

For both extraction approaches, there exist ready-to-use general purpose scripts:

- `extract-imga.py` extracts images page by page:

```python
# Extract Images

*** Scanning Pages ***
55 of 100
55 %

18.97 Iterations per Second
0.05 Seconds per Iteration

0:00:02 Elapsed Time
0:00:02 Time Remaining
0:00:05 Estimated Total Time

[ Cancel ]
```

and `extract-imgb.py` extracts images by xref table:
4.1.7 How to Handle Stencil Masks

Some images in PDFs are accompanied by **stencil masks**. In their simplest form stencil masks represent alpha (transparency) bytes stored as separate images. In order to reconstruct the original of an image, which has a stencil mask, it must be “enriched” with transparency bytes taken from its stencil mask.

Whether an image does have such a stencil mask can be recognized in one of two ways in PyMuPDF:

1. An item of `Document.get_page_images()` has the general format `[xref, smask, ...]`, where `xref` is the image’s xref and `smask`, if positive, is the xref of a stencil mask.

2. The (dictionary) results of `Document.extract_image()` have a key “smask”, which also contains any stencil mask’s xref if positive.

If `smask == 0` then the image encountered via `xref` can be processed as it is.

To recover the original image using PyMuPDF, the procedure depicted as follows must be executed:

```python
>>> pix1 = fitz.Pixmap(doc, xref)  # (1) pixmap of image w/o alpha
>>> pix2 = fitz.Pixmap(doc, smask)  # (2) stencil pixmap
>>> pix = fitz.Pixmap(pix1)  # (3) copy of pix1, empty alpha channel added
>>> pix.setAlpha(pix2.samples)  # (4) fill alpha channel
```

Step (1) creates a pixmap of the “netto” image. Step (2) does the same with the stencil mask. Please note that the `Pixmap.samples` attribute of `pix2` contains the alpha bytes that must be stored in the final pixmap. This is what happens in step (3) and (4).

4.1. Images
The scripts `extract-imga.py`, and `extract-imgb.py` above also contain this logic.

### 4.1.8 How to Make one PDF of all your Pictures (or Files)

We show here three scripts that take a list of (image and other) files and put them all in one PDF.

**Method 1: Inserting Images as Pages**

The first one converts each image to a PDF page with the same dimensions. The result will be a PDF with one page per image. It will only work for supported image file formats:

```python
import os
import PySimpleGUI as psg
# for showing a progress bar

doc = fitz.open()  # PDF with the pictures
imgdir = "D:/2012_10_05"  # where the pics are
imglist = os.listdir(imgdir)  # list of them
imgcount = len(imglist)  # pic count

for i, f in enumerate(imglist):
    img = fitz.open(os.path.join(imgdir, f))  # open pic as document
    rect = img[0].rect  # pic dimension
    pdfbytes = img.convert_to_pdf()  # make a PDF stream
    img.close()  # no longer needed
    imgPDF = fitz.open("pdf", pdfbytes)  # open stream as PDF
    page = doc.new_page(width = rect.width,  # new page with ...
                        height = rect.height)  # pic dimension
    page.show_pdf_page(rect, imgPDF, 0)  # image fills the page
    psg.EasyProgressMeter("Import Images",  # show our progress
                          i+1, imgcount)

doc.save("all-my-pics.pdf")
```

This will generate a PDF only marginally larger than the combined pictures’ size. Some numbers on performance:

The above script needed about 1 minute on my machine for 149 pictures with a total size of 514 MB (and about the same resulting PDF size).

Look here for a more complete source code: it offers a directory selection dialog and skips unsupported files and non-file entries.
Method 2: Embedding Files

The second script embeds arbitrary files – not only images. The resulting PDF will have just one (empty) page, required for technical reasons. To later access the embedded files again, you would need a suitable PDF viewer that can display and / or extract embedded files:

```python
import os, fitz
import PySimpleGUI as psg  # for showing progress bar

doc = fitz.open()  # PDF with the pictures
imgdir = "D:/2012_10_05"  # where my files are

imglist = os.listdir(imgdir)  # list of pictures
imgcount = len(imglist)  # pic count
imglist.sort()  # nicely sort them

for i, f in enumerate(imglist):
    img = open(os.path.join(imgdir, f), "rb").read()  # make pic stream
    doc.embfile_add(img, f, filename=f, ufilename=f, desc=f)  # and embed it
    psg.EasyProgressMeter("Embedding Files", i+1, imgcount)

page = doc.new_page()  # at least 1 page is needed

doc.save("all-my-pics-embedded.pdf")
```

This is by far the fastest method, and it also produces the smallest possible output file size. The above pictures needed 20 seconds on my machine and yielded a PDF size of 510 MB. Look [here](#) for a more complete source code: it offers a directory selection dialog and skips non-file entries.

Method 3: Attaching Files

A third way to achieve this task is attaching files via page annotations see [here](#) for the complete source code.

This has a similar performance as the previous script and it also produces a similar file size. It will produce PDF pages which show a ‘FileAttachment’ icon for each attached file.

4.1. Images
Note: Both, the `embed` and the `attach` methods can be used for arbitrary files – not just images.

Note: We strongly recommend using the awesome package PySimpleGUI to display a progress meter for tasks that may run for an extended time span. It’s pure Python, uses Tkinter (no additional GUI package) and requires just one more line of code!

### 4.1.9 How to Create Vector Images

The usual way to create an image from a document page is `Page.get_pixmap()`. A pixmap represents a raster image, so you must decide on its quality (i.e. resolution) at creation time. It cannot be changed later.

PyMuPDF also offers a way to create a vector image of a page in SVG format (scalable vector graphics, defined in XML syntax). SVG images remain precise across zooming levels (of course with the exception of any raster graphic elements embedded therein).

Instruction `svg = page.getSVGimage(matrix=fitz.Identity)` delivers a UTF-8 string `svg` which can be stored with extension “.svg”.

```

Page 1 of 3
4.1.10 How to Convert Images

Just as a feature among others, PyMuPDF’s image conversion is easy. It may avoid using other graphics packages like PIL/Pillow in many cases.

Notwithstanding that interfacing with Pillow is almost trivial.

</tr>
</tbody>
</table>

The general scheme is just the following two lines:

```
pix = fitz.Pixmap("input.xxx")  # any supported input format
pix.writeImage("output.yyy")   # any supported output format
```

Remarks

1. The input argument of fitz.Pixmap(arg) can be a file or a bytes / io.BytesIO object containing an image.
2. Instead of an output file, you can also create a bytes object via pix.getImageData("yyy") and pass this around.
3. As a matter of course, input and output formats must be compatible in terms of colorspace and transparency.
   The Pixmap class has batteries included if adjustments are needed.

**Note: Convert JPEG to Photoshop:**

```
pix = fitz.Pixmap("myfamily.jpg")
pix.writeImage("myfamily.psd")
```

**Note: Save to JPEG using PIL/Pillow:**

```
from PIL import Image
pix = fitz.Pixmap(...)
img = Image.frombytes("RGB", [pix.width, pix.height], pix.samples)
img.save("output.jpg", "JPEG")
```

**Note: Convert JPEG to Tkinter PhotoImage.** Any RGB / no-alpha image works exactly the same. Conversion to one of the Portable Anymap formats (PPM, PGM, etc.) does the trick, because they are supported by all Tkinter versions.
if str is bytes:  # this is Python 2!
    import Tkinter as tk
else:  # Python 3 or later!
    import tkinter as tk
pix = fitz.Pixmap("input.jpg")  # or any RGB / no-alpha image
tkimg = tk.PhotoImage(data=pix.getImageData("ppm"))

Note: Convert PNG with alpha to Tkinter PhotoImage. This requires removing the alpha bytes, before we can do the PPM conversion:

if str is bytes:  # this is Python 2!
    import Tkinter as tk
else:  # Python 3 or later!
    import tkinter as tk
pix = fitz.Pixmap("input.png")  # may have an alpha channel
if pix.alpha:  # we have an alpha channel!
    pix = fitz.Pixmap(pix, 0)  # remove it
    tkimg = tk.PhotoImage(data=pix.getImageData("ppm"))

4.1.11 How to Use Pixmaps: Gluing Images

This shows how pixmaps can be used for purely graphical, non-document purposes. The script reads an image file and creates a new image which consist of 3 * 4 tiles of the original:

import fitz
src = fitz.Pixmap("img-7edges.png")  # create pixmap from a picture
col = 3  # tiles per row
lin = 4  # tiles per column
tar_w = src.width * col  # width of target
tar_h = src.height * lin  # height of target

# create target pixmap
tar_pix = fitz.Pixmap(src.colorspace, (0, 0, tar_w, tar_h), src.alpha)

# now fill target with the tiles
for i in range(col):
    for j in range(lin):
        src.setOrigin(src.width * i, src.height * j)
        tar_pix.copyPixmap(src, src.irect)  # copy input to new loc

This is the input picture:

![Input Picture](image)

Here is the output:
4.1.12 How to Use Pixmaps: Making a Fractal

Here is another Pixmap example that creates Sierpinski’s Carpet – a fractal generalizing the Cantor Set to two dimensions. Given a square carpet, mark its 9 sub-squares (3 times 3) and cut out the one in the center. Treat each of the remaining eight sub-squares in the same way, and continue ad infinitum. The end result is a set with area zero and fractal dimension 1.8928…

This script creates a approximate image of it as a PNG, by going down to one-pixel granularity. To increase the image precision, change the value of n (precision):

```python
import fitz, time
if not list(map(int, fitz.VersionBind.split("."))) >= [1, 14, 8]:
    raise SystemExit("need PyMuPDF v1.14.8 for this script")

n = 6  # depth (precision)
d = 3**n  # edge length

t0 = time.perf_counter()  # the pixmap rectangle
ir = (0, 0, d, d)

pm = fitz.Pixmap(fitz.csRGB, ir, False)
pm.setRect(pm.irect, (255,255,0))  # fill it with some background color

color = (0, 0, 255)  # color to fill the punch holes

def punch(x, y, step):
    """Recursively "punch a hole" in the central square of a pixmap.""
    # alternatively, define a 'fill' pixmap for the punch holes
    # this could be anything, e.g. some photo image ...
    fill = fitz.Pixmap(fitz.csRGB, ir, False)  # same size as 'pm'
    fill.setRect(fill.irect, (0, 255, 255))  # put some color in
    fill.setRect(fill.irect, (0, 255, 255))  # put some color in
```

(continues on next page)
Arguments are top-left coords and the step width.

Some alternative punching methods are commented out.

```python
# the new step
for i in range(3):
    for j in range(3):
        if i != j or i != 1:
            if s >= 3:
                punch(x+i*s, y+j*s, s)
            else:
                pm.setRect((x+s, y+s, x+2*s, y+2*s), color)
        else:
            # punching alternatives are:
            pm.copyPixmap(fill, (x+s, y+s, x+2*s, y+2*s))
            pm.invertIRect((x+s, y+s, x+2*s, y+2*s))

return
```

# main program
# now start punching holes into the pixmap
punch(0, 0, d)
t1 = time.perf_counter()
pm.writeImage("sierpinski-punch.png")
t2 = time.perf_counter()
print ("%g sec to create / fill the pixmap" % round(t1-t0, 3))
print ("%g sec to save the image" % round(t2-t1, 3))

The result should look something like this:
4.1.13 How to Interface with NumPy

This shows how to create a PNG file from a numpy array (several times faster than most other methods):

```python
import numpy as np
import fitz

# create a fun-colored width * height PNG with fitz and numpy

height = 150
width = 100
bild = np.ndarray((height, width, 3), dtype=np.uint8)
for i in range(height):
    for j in range(width):
        # one pixel (some fun coloring)
        bild[i, j] = [(i+j)%256, i%256, j%256]

samples = bytearray(bild.tostring())  # get plain pixel data from numpy array
pix = fitz.Pixmap(fitz.csRGB, width, height, samples, alpha=False)
pix.writePNG("test.png")
```

4.1.14 How to Add Images to a PDF Page

There are two methods to add images to a PDF page: `Page.insertImage()` and `Page.show_pdf_page()`. Both methods have things in common, but there also exist differences.

<table>
<thead>
<tr>
<th>Criterion</th>
<th><code>Page.insertImage()</code></th>
<th><code>Page.show_pdf_page()</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>displayable content</td>
<td>image file, image in memory, pixmap</td>
<td>PDF page</td>

<td>yes (default option)</td>
<td>yes (default option)</td>
</tr>
<tr>
<td>transparency (water marking)</td>
<td>depends on image</td>
<td>yes</td>
</tr>
<tr>
<td>location / placement</td>
<td>scaled to fit target rectangle</td>
<td>scaled to fit target rectangle</td>
</tr>
<tr>
<td>performance</td>
<td>automatic prevention of duplicates; MD5 calculation on every execution</td>
<td>automatic prevention of duplicates; faster than <code>Page.insertImage()</code></td>
</tr>
<tr>
<td>multi-page image support</td>
<td>no</td>
<td>yes</td>
</tr>
<tr>
<td>ease of use</td>
<td>simple, intuitive; performance considerations apply for multiple insertions of same image</td>
<td>simple, intuitive; <strong>usable for all document types</strong> (including images!) after conversion to PDF via <code>Document.convert_to_pdf()</code></td>
</tr>
</tbody>
</table>

4.1. Images
Basic code pattern for `Page.insertImage()`. **Exactly one** of the parameters `filename` / `stream` / ` pixmap` must be given:

```python
page.insertImage(
    rect,   # where to place the image (rect-like)
    filename=None,      # image in a file
    stream=None,       # image in memory (bytes)
    pixmap=None,   # image from pixmap
    rotate=0,        # rotate (int, multiple of 90)
    keep_proportion=True,  # keep aspect ratio
    overlay=True,   # put in foreground
)
```

Basic code pattern for `Page.show_pdf_page()`. Source and target PDF must be different `Document` objects (but may be opened from the same file):

```python
page.show_pdf_page(
    rect,    # where to place the image (rect-like)
    src,     # source PDF
    pno=0,   # page number in source PDF
    clip=None, # only display this area (rect-like)
    rotate=0,   # rotate (float, any value)
    keep_proportion=True, # keep aspect ratio
    overlay=True, # put in foreground
)
```

## 4.2 Text

### 4.2.1 How to Extract all Document Text

This script will take a document filename and generate a text file from all of its text.

The document can be any supported type like PDF, XPS, etc.

The script works as a command line tool which expects the document filename supplied as a parameter. It generates one text file named “filename.txt” in the script directory. Text of pages is separated by a form feed character:

```python
import sys, fitz
fname = sys.argv[1]  # get document filename
doc = fitz.open(fname)  # open document
out = open(fname + ".txt", "wb")  # open text output
for page in doc:  # iterate the document pages
    text = page.get_text().encode("utf8")  # get plain text (is in UTF-8)
    out.write(text)  # write text of page
    out.write(bytes((12,)))  # write page delimiter (form feed 0x0C)
out.close()
```

The output will be plain text as it is coded in the document. No effort is made to prettify in any way. Specifically for PDF, this may mean output not in usual reading order, unexpected line breaks and so forth.

You have many options to cure this – see chapter *Appendix 2: Details on Text Extraction*. Among them are:

1. Extract text in HTML format and store it as a HTML document, so it can be viewed in any browser.
2. Extract text as a list of text blocks via `Page.get_text("blocks")`. Each item of this list contains position information for its text, which can be used to establish a convenient reading order.

3. Extract a list of single words via `Page.get_text("words")`. Its items are words with position information. Use it to determine text contained in a given rectangle – see next section.

See the following two section for examples and further explanations.

### 4.2.2 How to Extract Text from within a Rectangle

There is now (v1.18.0) more than one way to achieve this. We therefore have created a folder in the PyMuPDF-Utilities repository specifically dealing with this topic.

### 4.2.3 How to Extract Text in Natural Reading Order

One of the common issues with PDF text extraction is, that text may not appear in any particular reading order. Responsible for this effect is the PDF creator (software or a human). For example, page headers may have been inserted in a separate step – after the document had been produced. In such a case, the header text will appear at the end of a page text extraction (although it will be correctly shown by PDF viewer software). For example, the following snippet will add some header and footer lines to an existing PDF:

```python
doc = fitz.open("some.pdf")
header = "Header"  # text in header
footer = "Page %i of %i"  # text in footer
for page in doc:
    page.insertText((50, 50), header)  # insert header
    page.insertText((50, page.rect.height - 50),
                    footer % (page.number + 1, len(doc)),
                    )
```

The text sequence extracted from a page modified in this way will look like this:

1. original text
2. header line
3. footer line

PyMuPDF has several means to re-establish some reading sequence or even to re-generate a layout close to the original. As a starting point take the above mentioned script and then use the full page rectangle.

On rare occasions, when the PDF creator has been “over-creative”, extracted text does not even keep the correct reading sequence of **single letters**: instead of the two words “DELUXE PROPERTY” you might sometimes get an anagram, consisting of 8 words like “DEL”, “XE”, “P”, “OP”, “RTY”, “U”, “R” and “E”.

Such a PDF is also not searchable by all PDF viewers, but it is displayed correctly and looks harmless.

In those cases, the following function will help composing the original words of the page. The resulting list is also searchable and can be used to deliver rectangles for the found text locations:

```python
from operator import itemgetter
from itertools import groupby
import fitz
```

(continues on next page)
def recover(words, rect):
    """Word recovery.

    Notes:
    Method 'get_textWords()' does not try to recover words, if their single
    letters do not appear in correct lexical order. This function steps in
    here and creates a new list of recovered words.

    Args:
    words: list of words as created by 'get_textWords()'
    rect: rectangle to consider (usually the full page)

    Returns:
    List of recovered words. Same format as 'get_text_words', but left out
    block, line and word number - a list of items of the following format:
    [x0, y0, x1, y1, "word"]
    """
    # build my sublist of words contained in given rectangle
    mywords = [w for w in words if fitz.Rect(w[:4]) in rect]

    # sort the words by lower line, then by word start coordinate
    mywords.sort(key=itemgetter(3, 0))  # sort by y1, x0 of word rectangle

    # build word groups on same line
    grouped_lines = groupby(mywords, key=itemgetter(3))

    words_out = []  # we will return this

    # iterate through the grouped lines
    # for each line coordinate ("_") , the list of words is given
    for _, words_in_line in grouped_lines:
        for i, w in enumerate(words_in_line):
            if i == 0:
                # store first word
                x0, y0, x1, y1, word = w[:5]
                continue

            r = fitz.Rect(w[:4])  # word rect

            # Compute word distance threshold as 20% of width of 1 letter.
            # So we should be safe joining text pieces into one word if they
            # have a distance shorter than that.
            threshold = r.width / len(w[4]) / 5
            if r.x0 <= x1 + threshold:  # join with previous word
                word += w[4]  # add string
                x1 = r.x1  # new end-of-word coordinate
                y0 = max(y0, r.y0)  # extend word rect upper bound
                continue

            # now have a new word, output previous one
            words_out.append([x0, y0, x1, y1, word])

            # store the new word
            x0, y0, x1, y1, word = w[:5]

            # output word waiting for completion
            words_out.append([x0, y0, x1, y1, word])

    return words_out
def search_for(text, words):
    """ Search for text in items of list of words
    
    Notes:
    Can be adjusted / extended in obvious ways, e.g. using regular
    expressions, or being case insensitive, or only looking for complete
    words, etc.
    
    Args:
    text: string to be searched for
    words: list of items in format delivered by 'get_text_words()'.
    
    Returns:
    List of rectangles, one for each found locations.
    """
    rect_list = []
    for w in words:
        if text in w[4]:
            rect_list.append(fitz.Rect(w[4]))
    return rect_list

4.2.4 How to Extract Tables from Documents

If you see a table in a document, you are not normally looking at something like an embedded Excel or other identifiable object. It usually is just text, formatted to appear as appropriate.

Extracting a tabular data from such a page area therefore means that you must find a way to (1) graphically indicate table and column borders, and (2) then extract text based on this information.

The wxPython GUI script wxTableExtract.py strives to exactly do that. You may want to have a look at it and adjust it to your liking.

4.2.5 How to Mark Extracted Text

There is a standard search function to search for arbitrary text on a page: Page.search_for(). It returns a list of Rect objects which surround a found occurrence. These rectangles can for example be used to automatically insert annotations which visibly mark the found text.

This method has advantages and drawbacks. Pros are

- The search string can contain blanks and wrap across lines
- Upper or lower case characters are treated equal
- Word hyphenation at line ends is detected and resolved
- return may also be a list of Quad objects to precisely locate text that is not parallel to either axis – using Quad output is also recommend, when page rotation is not zero.

But you also have other options:
import sys
import fitz

def mark_word(page, text):
    """Underline each word that contains 'text'.""
    found = 0
    wlist = page.getTex("words")  # make the word list
    for w in wlist:  # scan through all words on page
        if text in w[4]:  # w[4] is the word's string
            found += 1  # count
            r = fitz.Rect(w[:4])  # make rect from word bbox
            page.addUnderlineAnnot(r)  # underline
    return found

fname = sys.argv[1]  # filename
text = sys.argv[2]  # search string
doc = fitz.open(fname)

print("underlining words containing '"s' in document '"s'" % (text, doc.name))

new_doc = False  # indicator if anything found at all
for page in doc:  # scan through the pages
    found = mark_word(page, text)  # mark the page's words
    if found:  # if anything found ...
        new_doc = True
        print("found '"s' %i times on page %i" % (text, found, page.number + 1))

if new_doc:
    doc.save("marked-" + doc.name)

This script uses `Page.get_text("words")` to look for a string, handed in via cli parameter. This method separates a page’s text into “words” using spaces and line breaks as delimiters. Therefore the words in this lists do not contain these characters. Further remarks:

- If found, the complete word containing the string is marked (underlined) – not only the search string.
- The search string may not contain spaces or other white space.
- As shown here, upper / lower cases are respected. But this can be changed by using the string method `lower()` (or even regular expressions) in function `mark_word`.
- There is no upper limit: all occurrences will be detected.
- You can use anything to mark the word: ‘Underline’, ‘Highlight’, ‘StrikeThrough’ or ‘Square’ annotations, etc.
- Here is an example snippet of a page of this manual, where “MuPDF” has been used as the search string. Note that all strings containing “MuPDF” have been completely underlined (not just the search string).
PyMuPDF runs and has been tested on Mac, Linux, Windows XP SP2 and up, Python 3.7 (note that Python supports Windows XP only up to v3.4), 32bit and 64bit should work too, as long as MuPDF and Python support them.

PyMuPDF is hosted on GitHub. We also are registered on PyPI.

For MS Windows and popular Python versions on Mac OSX and Linux we have creation should be convenient enough for hopefully most of our users: just issue pip install --upgrade pymupdf

If your platform is not among those supported with a wheel, your installation steps:

---

3. https://github.com/ri700/PyMuPDF
4. https://pypi.org/project/PyMuPDF/

---

### 4.2.6 How to Mark Searched Text

This script searches for text and marks it:

```python
# -*- coding: utf-8 -*-
import fitz

# the document to annotate
doc = fitz.open("tilted-text.pdf")

# the text to be marked
t = "¡La práctica hace el campeón!"

# work with first page only
page = doc[0]

# get list of text locations
# we use "quads", not rectangles because text may be tilted!
rl = page.search_for(t, quads = True)

# mark all found quads with one annotation
page.addSquigglyAnnot(rl)

# save to a new PDF
doc.save("a-squiggly.pdf")
```

The result looks like this:
4.2.7 How to Mark Non-horizontal Text

The previous section already shows an example for marking non-horizontal text detected by text searching.

But text extraction with the “dict” option of `Page.get_text()` may also return text with a non-zero angle to the x-axis. This is reflected by the value of the "dir" key of the line dictionary: it is the tuple \((\cosine, \text{sine})\) of that angle.

Currently, all bboxes returned by the method’s are rectangles only – no quads. So we can mark the span text (correctly) only, if the angle is 0, 90, 180 or 270 degrees.

In this case we can convert the span bbox into the right quad by choosing the right sequence of its corners:

```python
r = fitz.Rect(span["bbox"])  
if line["dir"] == (1, 0):  # rotation 0
    q = fitz.Quad(r)
elif line["dir"] == (0, -1):  # rotation 90
    q = fitz.Quad(r.bl, r.tl, r.br, r.tr)
elif line["dir"] == (-1, 0):  # rotation 180
    q = fitz.Quad(r.br, r.bl, r.tr, r.tl)
elif line["dir"] == (0, 1):  # rotation 270
    q = fitz.Quad(r.tr, r.br, r.tl, r.bl)
else:
    q = fitz.Quad(r)
    print("warning: unsupported text flow")

annot = page.addHighlightAnnot(q)
```
4.2.8 How to Analyze Font Characteristics

To analyze the characteristics of text in a PDF use this elementary script as a starting point:

```python
import fitz

def flags_decomposer(flags):
    """Make font flags human readable."""
    l = []
    if flags & 2 ** 0:
        l.append("superscript")
    if flags & 2 ** 1:
        l.append("italic")
    if flags & 2 ** 2:
        l.append("serifed")
    else:
        l.append("sans")
    if flags & 2 ** 3:
        l.append("monospaced")
    else:
        l.append("proportional")
    if flags & 2 ** 4:
        l.append("bold")
    return ", " . join(l)

doc = fitz.open("text-tester.pdf")
page = doc[0]

# read page text as a dictionary, suppressing extra spaces in CJK fonts
blocks = page.get_text("dict", flags=11)["blocks"
for b in blocks:  # iterate through the text blocks
    for l in b["lines"]:  # iterate through the text lines
        for s in l["spans"]:  # iterate through the text spans
            print("
            font_properties = "Font: '" + s["font"] + "', size \$s\$g, color \$%06x\$ %" + s["color"],  # font name
                " readable font flags
            print("Text: '" + s["text"] + "'", font_properties)
```

Here is the PDF page and the script output:
4.2.9 How to Insert Text

PyMuPDF provides ways to insert text on new or existing PDF pages with the following features:

- choose the font, including built-in fonts and fonts that are available as files
- choose text characteristics like bold, italic, font size, font color, etc.
- position the text in multiple ways:
  - either as simple line-oriented output starting at a certain point,
  - or fitting text in a box provided as a rectangle, in which case text alignment choices are also available,
  - choose whether text should be put in foreground (overlay existing content),
  - all text can be arbitrarily “morphed”, i.e. its appearance can be changed via a Matrix, to achieve effects like scaling, shearing or mirroring,
  - independently from morphing and in addition to that, text can be rotated by integer multiples of 90 degrees.

All of the above is provided by three basic `Page`, resp. `Shape` methods:

- `Page.insertFont()` – install a font for the page for later reference. The result is reflected in the output of `Document.get_page_fonts()`. The font can be:
  - provided as a file,
  - already present somewhere in this or another PDF, or
  - be a built-in font.
- `Page.insertText()` – write some lines of text. Internally, this uses `Shape.insertText()`.
• Page.insertTextbox() – fit text in a given rectangle. Here you can choose text alignment features (left, right, centered, justified) and you keep control as to whether text actually fits. Internally, this uses Shape.insertTextbox().

Note: Both text insertion methods automatically install the font as necessary.

4.2.9.1 How to Write Text Lines

Output some text lines on a page:

```python
import fitz
doc = fitz.open(...)  # new or existing PDF
page = doc.new_page()  # new or existing page via doc[n]
p = fitz.Point(50, 72)  # start point of 1st line

text = "Some text, \n spread across \n several lines."
# the same result is achievable by
# text = ["Some text", "spread across", "several lines."]

rc = page.insertText(p,  # bottom-left of 1st char
    text,  # the text (honors '\n')
    fontname = "helv",  # the default font
    fontsize = 11,  # the default font size
    rotate = 0,  # also available: 90, 180, 270
)

print("%i lines printed on page %i." % (rc, page.number))

doc.save("text.pdf")
```

With this method, only the number of lines will be controlled to not go beyond page height. Surplus lines will not be written and the number of actual lines will be returned. The calculation uses $1.2 \times \text{fontsize}$ as the line height and 36 points (0.5 inches) as bottom margin.

Line width is ignored. The surplus part of a line will simply be invisible.

However, for built-in fonts there are ways to calculate the line width beforehand - see `getTextlength()`.

Here is another example. It inserts 4 text strings using the four different rotation options, and thereby explains, how the text insertion point must be chosen to achieve the desired result:

```python
import fitz
doc = fitz.open()
page = doc.new_page()
# the text strings, each having 3 lines
text1 = "rotate=0 \n Line 2 \n Line 3"

# rotate=90
text2 = "rotate=90 \n Line 2 \n Line 3"

# rotate=-90
text3 = "rotate=-90 \n Line 2 \n Line 3"

# rotate=180
text4 = "rotate=180 \n Line 2 \n Line 3"

red = (1, 0, 0)  # the color for the red dots
# the insertion points, each with a 25 pix distance from the corners
p1 = fitz.Point(25, 25)
p2 = fitz.Point(page.rect.width - 25, 25)
p3 = fitz.Point(25, page.rect.height - 25)

# create a Shape to draw on
shape = page.newShape()
```

(continues on next page)
# draw the insertion points as red, filled dots
shape.draw_circle(p1,1)
shape.draw_circle(p2,1)
shape.draw_circle(p3,1)
shape.draw_circle(p4,1)
shape.finish(width=0.3, color=red, fill=red)

# insert the text strings
shape.insertText(p1, text1)
shape.insertText(p3, text2, rotate=90)
shape.insertText(p2, text3, rotate=-90)
shape.insertText(p4, text4, rotate=180)

# store our work to the page
shape.commit()
doc.save(...)

This is the result:

![Diagram showing text rotated by 0, 90, -90, and 180 degrees]

4.2.9.2 How to Fill a Text Box

This script fills 4 different rectangles with text, each time choosing a different rotation value:

```python
import fitz
doc = fitz.open(...)  # new or existing PDF
page = doc.new_page()  # new page, or choose doc[n]
r1 = fitz.Rect(50,100,100,150)  # a 50x50 rectangle
disp = fitz.Rect(55, 0, 55, 0)  # add this to get more rects
r2 = r1 + disp  # 2nd rect
r3 = r1 + disp * 2  # 3rd rect
r4 = r1 + disp * 3  # 4th rect
t1 = "text with rotate = 0."  # the texts we will put in
t2 = "text with rotate = 90."
t3 = "text with rotate = -90."
t4 = "text with rotate = 180."
red = (1,0,0)  # some colors
```
```python
gold = (1,1,0)
blue = (0,0,1)

"""We use a Shape object (something like a canvas) to output the text and
the rectangles surrounding it for demonstration.
"""
shape = page.newShape()  # create Shape
shape.draw_rect(r1)      # draw rectangles
shape.draw_rect(r2)      # giving them
shape.draw_rect(r3)      # a yellow background
shape.draw_rect(r4)      # and a red border
shape.finish(width = 0.3, color = red, fill = gold)  # Now insert text in the rectangles. Font "Helvetica" will be used
# by default. A return code rc < 0 indicates insufficient space (not checked here).
rc = shape.insertTextbox(r1, t1, color = blue)
rc = shape.insertTextbox(r2, t2, color = blue, rotate = 90)
rc = shape.insertTextbox(r3, t3, color = blue, rotate = -90)
rc = shape.insertTextbox(r4, t4, color = blue, rotate = 180)
shape.commit()   # write all stuff to page /Contents
doc.save("...")
```

Several default values were used above: font “Helvetica”, font size 11 and text alignment “left”. The result will look like this:

![Text with different rotations](image)

**4.2.9.3 How to Use Non-Standard Encoding**

Since v1.14, MuPDF allows Greek and Russian encoding variants for the Base14_Fonts. In PyMuPDF this is supported via an additional `encoding` argument. Effectively, this is relevant for Helvetica, Times-Roman and Courier (and their bold / italic forms) and characters outside the ASCII code range only. Elsewhere, the argument is ignored. Here is how to request Russian encoding with the standard font Helvetica:

```python
page.insertText(point, russian_text, encoding=fitz.TEXT_ENCODING_CYRILLIC)
```

The valid encoding values are TEXT_ENCODING_LATIN (0), TEXT_ENCODING_GREEK (1), and TEXT_ENCODING_CYRILLIC (2, Russian) with Latin being the default. Encoding can be specified by all relevant font and text insertion methods.

By the above statement, the fontname *helv* is automatically connected to the Russian font variant of Helvetica. Any subsequent text insertion with **this fontname** will use the Russian Helvetica encoding.

If you change the fontname just slightly, you can also achieve an **encoding “mixture”** for the **same base font** on the same page:

```python
import fitz
doc=fitz.open()
page = doc.new_page()
shape = page.newShape()
t="Sômé tèxt wìth nöñ-Lâtîn characterß."
```
The snippet above indeed leads to three different copies of the Helvetica font in the PDF. Each copy is uniquely identified (and referenceable) by using the correct upper-lower case spelling of the reserved word “helv”:

```python
for f in doc.get_page_fonts(0): print(f)
[6, 'n/a', 'Type1', 'Helvetica', 'helv', 'WinAnsiEncoding']
[7, 'n/a', 'Type1', 'Helvetica', 'HElv', 'WinAnsiEncoding']
[8, 'n/a', 'Type1', 'Helvetica', 'HELV', 'WinAnsiEncoding']
```

4.3 Annotations

In v1.14.0, annotation handling has been considerably extended:

- New annotation type support for ‘Ink’, ‘Rubber Stamp’ and ‘Squiggly’ annotations. Ink annots simulate handwriting by combining one or more lists of interconnected points. Stamps are intended to visually inform about a document’s status or intended usage (like “draft”, “confidential”, etc.). ‘Squiggly’ is a text marker annot, which underlines selected text with a zigzagged line.

- Extended ‘FreeText’ support:
  1. all characters from the *Latin* character set are now available,
  2. colors of text, rectangle background and rectangle border can be independently set
  3. text in rectangle can be rotated by either +90 or -90 degrees
  4. text is automatically wrapped (made multi-line) in available rectangle
  5. all Base-14 fonts are now available (*normal* variants only, i.e. no bold, no italic).

- MuPDF now supports line end icons for ‘Line’ annots (only). PyMuPDF supported that in v1.13.x already – and for (almost) the full range of applicable types. So we adjusted the appearance of ‘Polygon’ and ‘PolyLine’ annots to closely resemble the one of MuPDF for ‘Line’.

- MuPDF now provides its own annotation icons where relevant. PyMuPDF switched to using them (for ‘FileAttachment’ and ‘Text’ [“sticky note”] so far).

- MuPDF now also supports ‘Caret’, ‘Movie’, ‘Sound’ and ‘Signature’ annotations, which we may include in PyMuPDF at some later time.
4.3.1 How to Add and Modify Annotations

In PyMuPDF, new annotations can be added via Page methods. Once an annotation exists, it can be modified to a large extent using methods of the Annot class.

In contrast to many other tools, initial insert of annotations happens with a minimum number of properties. We leave it to the programmer to e.g. set attributes like author, creation date or subject.

As an overview for these capabilities, look at the following script that fills a PDF page with most of the available annotations. Look in the next sections for more special situations:

```python
# -*- coding: utf-8 -*-

""
Demo script showing how annotations can be added to a PDF using PyMuPDF.
It contains the following annotation types:
Caret, Text, FreeText, text markers (underline, strike-out, highlight, squiggle), Circle, Square, Line, PolyLine, Polygon, FileAttachment, Stamp and Redaction.
There is some effort to vary appearances by adding colors, line ends, opacity, rotation, dashed lines, etc.

(continues on next page)

4.3. Annotations 43
This script should lead to the following output:
4.3.2 How to Use FreeText

This script shows a couple of ways to deal with ‘FreeText’ annotations:

```python
# coding: utf-8
import fitz

# some colors
blue = (0,0,1)
green = (0,1,0)
red = (1,0,0)
gold = (1,1,0)

# a new PDF with 1 page
doc = fitz.open()
page = doc.new_page()

# 3 rectangles, same size, above each other
r1 = fitz.Rect(100,100,200,150)
r2 = r1 + (0,75,0,75)
r3 = r2 + (0,75,0,75)

# the text, Latin alphabet
t = "¡Un pequeño texto para practicar!"

# add 3 annots, modify the last one somewhat
a1 = page.addFreetextAnnot(r1, t, color=red)
a2 = page.addFreetextAnnot(r2, t, fontname="Ti", color=blue)
a3 = page.addFreetextAnnot(r3, t, fontname="Co", color=blue, rotate=90)
a3.setBorder(width=0)
a3.update(fontsize=8, fill_color=gold)

# save the PDF
doc.save("a-freetext.pdf")
```

The result looks like this:

```
¡Un pequeño texto para practicar!
```

```
¡Un pequeño texto para practicar!
```

```
¡Un pequeño texto para practicar!
```

4.3. Annotations
4.3.3 Using Buttons and JavaScript

Since MuPDF v1.16, ‘FreeText’ annotations no longer support bold or italic versions of the Times-Roman, Helvetica or Courier fonts.

A big thank you to our user @kurokawaikki, who contributed the following script to circumvent this restriction.

```python
import sys
import fitz

# this JavaScript will execute when the button is clicked:
jscript = ""
var annt = this.getAnnots();
annt.forEach(function (item, index) {
    try {
        var span = item.richContents;
        span.forEach(function (it, dx) {
            it.fontWeight = 800;
        })
        item.richContents = span;
    } catch (err) {}}
});
app.alert('Done');
"
```

(continues on next page)
4.3.4 How to Use Ink Annotations

Ink annotations are used to contain freehand scribbling. A typical example maybe an image of your signature consisting of first name and last name. Technically an ink annotation is implemented as a list of lists of points. Each point list is regarded as a continuous line connecting the points. Different point lists represent independent line segments of the annotation.

The following script creates an ink annotation with two mathematical curves (sine and cosine function graphs) as line segments:

```python
import math
import fitz

# preliminary stuff: create function value lists for sine and cosine
w360 = math.pi * 2  # go through full circle
deg = w360 / 360  # 1 degree as radians
rect = fitz.Rect(100, 200, 300, 300)  # use this rectangle
first_x = rect.x0  # x starts from left
first_y = rect.y0 + rect.height / 2.  # rect middle means y = 0
x_step = rect.width / 360  # rect width means 360 degrees
y_scale = rect.height / 2.  # rect height means 2
sin_points = []  # sine values go here
cos_points = []  # cosine values go here
for x in range(362):  # now fill in the values
    x_coord = x * x_step + first_x  # current x coordinate
    sin_points.append(math.sin(x * deg) * y_scale)
    cos_points.append(math.cos(x * deg) * y_scale)
```

(continues on next page)
y = -math.sin(x * deg)  # sine
p = (x_coord, y * y_scale + first_y)  # corresponding point
sin_points.append(p)  # append
y = -math.cos(x * deg)  # cosine
p = (x_coord, y * y_scale + first_y)  # corresponding point
cos_points.append(p)  # append

# create the document with one page
# doc = fitz.open()  # make new PDF
page = doc.new_page()  # give it a page

# add the Ink annotation, consisting of 2 curve segments
annot = page.addInkAnnot((sin_points, cos_points))
annot.setBorder(width=0.3, dashes=[1,])  # line thickness, some dashing
annot.setColors(stroke=(0,0,1))  # make the lines blue
annot.update()  # update the appearance

page.draw_rect(rect, width=0.3)  # only to demonstrate we did OK

This is the result:

![Result Image]

4.4 Drawing and Graphics

PDF files support elementary drawing operations as part of their syntax. This includes basic geometrical objects like lines, curves, circles, rectangles including specifying colors.

The syntax for such operations is defined in “A Operator Summary” on page 985 of the Adobe PDF References. Specifying these operators for a PDF page happens in its contents objects.

PyMuPDF implements a large part of the available features via its Shape class, which is comparable to notions like “canvas” in other packages (e.g. reportlab).

A shape is always created as a child of a page, usually with an instruction like shape = page.newShape(). The class defines numerous methods that perform drawing operations on the page’s area. For example, last_point = shape.draw_rect(rect) draws a rectangle along the borders of a suitably defined rect = fitz.Rect(...).
The returned `last_point` *always* is the `Point` where drawing operation ended ("last point"). Every such elementary drawing requires a subsequent `Shape.finish()` to "close" it, but there may be multiple drawings which have one common `finish()` method.

In fact, `Shape.finish()` *defines* a group of preceding draw operations to form one – potentially rather complex – graphics object. PyMuPDF provides several predefined graphics in `shapes_and_symbols.py` which demonstrate how this works.

If you import this script, you can also directly use its graphics as in the following example:

```python
# -*- coding: utf-8 -*-

Created on Sun Dec  9 08:34:06 2018
@author: Jorj
@license: GNU GPL 3.0+

Create a list of available symbols defined in shapes_and_symbols.py
This also demonstrates an example usage: how these symbols could be used
as bullet-point symbols in some text.

```python
import fitz
import shapes_and_symbols as sas

# list of available symbol functions and their descriptions
list = [
    (sas.arrow, "arrow (easy)"),
    (sas.caro, "caro (easy)"),
    (sas.clover, "clover (easy)"),
    (sas.diamond, "diamond (easy)"),
    (sas.dontenter, "do not enter (medium)"),
    (sas.frowney, "frowney (medium)"),
    (sas.hand, "hand (complex)"),
    (sas.heart, "heart (easy)"),
    (sas.pencil, "pencil (very complex)"),
    (sas.smiley, "smiley (easy)"),
]

r = fitz.Rect(50, 50, 100, 100)  # first rect to contain a symbol
r = fitz.Rect(0, r.height + 10, 0, r.height + 10)  # displacement to next rect
r = (15, -r.height * 0.2)  # starting point of explanation text
rlist = [r]  # rectangle list

for i in range(1, len(tlist)):  # fill in all the rectangles
    rlist.append(rlist[i-1] + d)

rlist = [r]  # rectangle list

do = fitz.open()  # create empty PDF
page = do.new_page()  # create an empty page
shape = page.newShape()  # start a Shape (canvas)

for i, r in enumerate(rlist):
    tlist[i][0](shape, rlist[i])  # execute symbol creation
    shape.insertText(rlist[i].br + p,  # insert description text
tlist[i][1], fontsize=r.height/1.2)
```

(continues on next page)
This is the script’s outcome:

- arrow (easy)
- caro (easy)
- clover (easy)
- diamond (easy)
- do not enter (medium)
- frowney (medium)
- hand (complex)
- heart (easy)
- pencil (very complex)
- smiley (easy)

### 4.5 Extracting Drawings

(New in v1.18.0)

The drawing commands issued by a page can be extracted. Interestingly, this is possible for all supported document types – not just PDF: so you can use it for XPS, EPUB and others as well.

A new page method, `Page.getDrawings()` accesses draw commands and converts them into a list of Python dictionaries. Each dictionary – called a “path” – represents a separate drawing – it may be simple like a single line, or a complex combination of lines and curves representing one of the shapes of the previous section.

The path dictionary has been designed such that it can easily be used by the `Shape` class and its methods.

The following is a code snippet which extracts the drawings of a page and re-draws them on a new page:

```python
import fitz
doc = fitz.open("some.file")
page = doc[0]
```
paths = page.getDrawings()  # extract existing drawings
# this is a list of "paths", which can directly be drawn again using Shape
# ---------------------------------------------------------------------------
# def define some output page with the same dimensions
outpdf = fitz.open()
outpage = outpdf.new_page(width=page.rect.width, height=page.rect.height)
shape = outpage.newShape()  # make a drawing canvas for the output page
# ---------------------------------------------------------------------------
# loop through the paths and draw them
# ---------------------------------------------------------------------------
for path in paths:
    # draw each entry of the 'items' list
    # ------------------------------------------------------------------------
    for item in path["items"]:  # these are the draw commands
        if item[0] == "l":  # line
            shape.draw_line(item[1], item[2])
        elif item[0] == "re":  # rectangle
            shape.draw_rect(item[1])
        elif item[0] == "c":  # curve
            shape.drawBezier(item[1], item[2], item[3], item[4])
        else:
            raise ValueError("unhandled drawing", item)
    # ------------------------------------------------------
    # all items are drawn, now apply the common properties
    # to finish the path
    # ------------------------------------------------------
    shape.finish(
        fill=path["fill"],  # fill color
        color=path["color"],  # line color
        dashes=path["dashes"],  # line dashing
        even_odd=path["even_odd"],  # control color of overlaps
        closePath=path["closePath"],  # whether to connect last and first point
        lineJoin=path["lineJoin"],  # how line joins should look like
        lineCap=max(path["lineCap"]),  # how line ends should look like
        width=path["width"],  # line width
        stroke_opacity=path["opacity"],  # same value for both
        fill_opacity=path["opacity"],  # opacity parameters
    )
    # all paths processed - commit the shape to its page
shape.commit()
outpdf.save("drawings-page-0.pdf")

As can be seen, there is a high congruence level with the Shape class. With one exception: For technical reasons lineCap is a tuple of 3 numbers here, whereas it is an integer in Shape (and in PDF). So we simply take the maximum value of that tuple.

Here is a comparison between input and output of an example page, created by the previous script:
Note: The reconstruction of graphics like shown here is not perfect. The following aspects will not be reproduced as of this version:

- Page definitions can be complex and include instructions for not showing / hiding certain areas to keep them invisible. Things like this are ignored by `Page.getDrawings()` - it will always return all paths.

Note: You can use the path list to make your own lists of e.g. all lines or all rectangles on the page, subselect them by criteria like color or position on the page etc.

### 4.6 Multiprocessing

MuPDF has no integrated support for threading - they call themselves “threading-agnostic”. While there do exist tricky possibilities to still use threading with MuPDF, the baseline consequence for **PyMuPDF** is:

**No Python threading support.**

Using PyMuPDF in a Python threading environment will lead to blocking effects for the main thread.

However, there exists the option to use Python’s `multiprocessing` module in a variety of ways.

If you are looking to speed up page-oriented processing for a large document, use this script as a starting point. It should be at least twice as fast as the corresponding sequential processing.

```
Demonstrate the use of multiprocessing with PyMuPDF.

Depending on the number of CPUs, the document is divided in page ranges. Each range is then worked on by one process. The type of work would typically be text extraction or page rendering. Each
```

(continues on next page)
process must know where to put its results, because this processing pattern
does not include inter-process communication or data sharing.

Compared to sequential processing, speed improvements in range of 100% (ie.
twice as fast) or better can be expected.

```python
from __future__ import print_function, division
import sys
import os
import time
from multiprocessing import Pool, cpu_count
import fitz

# choose a version specific timer function (bytes == str in Python 2)
mytime = time.clock if str is bytes else time.perf_counter

def render_page(vector):
    ""
    Render a page range of a document.
    
    Notes:
    The PyMuPDF document cannot be part of the argument, because that
cannot be pickled. So we are being passed in just its filename.
    This is no performance issue, because we are a separate process and
need to open the document anyway.
    Any page-specific function can be processed here - rendering is just
an example - text extraction might be another.
    The work must however be self-contained: no inter-process communication
or synchronization is possible with this design.
    Care must also be taken with which parameters are contained in the
argument, because it will be passed in via pickling by the Pool class.
    So any large objects will increase the overall duration.
    
    Args:
    vector: a list containing required parameters.
    ""
    # recreate the arguments
    idx = vector[0]  # this is the segment number we have to process
    cpu = vector[1]  # number of CPUs
    filename = vector[2]  # document filename
    mat = vector[3]  # the matrix for rendering
    doc = fitz.open(filename)  # open the document
    num_pages = len(doc)  # get number of pages
    # pages per segment: make sure that cpu * seg_size >= num_pages!
    seg_size = int(num_pages / cpu + 1)
    seg_from = idx * seg_size  # our first page number
    seg_to = min(seg_from + seg_size, num_pages)  # last page number

    for i in range(seg_from, seg_to):
        # work through our page segment
        page = doc[i]
        # page.get_text("rawdict")  # use any page-related type of work here, eg
        pix = page.get_pixmap(alpha=False, matrix=mat)
        # store away the result somewhere ...
        # pix.writePNG("p-%i.png" % i)
        print("Processed page numbers %i through %i" % (seg_from, seg_to - 1))
```

(continues on next page)
```python
if __name__ == '__main__':
    t0 = mytime()  # start a timer
    filename = sys.argv[1]
    mat = fitz.Matrix(0.2, 0.2)  # the rendering matrix: scale down to 20%
    cpu = cpu_count()

    # make vectors of arguments for the processes
    vectors = [(i, cpu, filename, mat) for i in range(cpu)]
    print("Starting %i processes for '%s'." % (cpu, filename))

    pool = Pool()  # make pool of 'cpu_count()' processes
    pool.map(render_page, vectors, 1)  # start processes passing each a vector

    t1 = mytime()  # stop the timer
    print("Total time \%g seconds" % round(t1 - t0, 2))
```

Here is a more complex example involving inter-process communication between a main process (showing a GUI) and a child process doing PyMuPDF access to a document.

```python
"""

  app = QtWidgets.QApplication(sys.argv)
  form = DocForm()
  sys.exit(app.exec_())
```

## 4.7 General

### 4.7.1 How to Open with a Wrong File Extension

If you have a document with a wrong file extension for its type, you can still correctly open it.

Assume that “some.file” is actually an XPS. Open it like so:

```python
>>> doc = fitz.open("some.file", filetype = "xps")
```

**Note:** MuPDF itself does not try to determine the file type from the file contents. You are responsible for supplying the filetype info in some way – either implicitly via the file extension, or explicitly as shown. There are pure Python packages like [filetype](https://pypi.org/project/filetype) that help you doing this. Also consult the [Document](https://pymupdf.readthedocs.io/en/latest/document.html) chapter for a full description.

### 4.7.2 How to Embed or Attach Files

PDF supports incorporating arbitrary data. This can be done in one of two ways: “embedding” or “attaching”. PyMuPDF supports both options.

1. Attached Files: data are **attached to a page** by way of a `FileAttachment` annotation with this statement: `annot = page.addFileAnnot(pos, . . . )`, for details see `Page.addFileAnnot()`. The first parameter “pos” is the `Point`, where a “PushPin” icon should be placed on the page.

2. Embedded Files: data are embedded on the **document level** via method `Document.embfile_add()`.
The basic differences between these options are (1) you need edit permission to embed a file, but only annotation permission to attach, (2) like all annotations, attachments are visible on a page, embedded files are not.

There exist several example scripts: embedded-list.py, new-annots.py.

Also look at the sections above and at chapter Appendix 3: Considerations on Embedded Files.

### 4.7.3 How to Delete and Re-Arrange Pages

With PyMuPDF you have all options to copy, move, delete or re-arrange the pages of a PDF. Intuitive methods exist that allow you to do this on a page-by-page level, like the `Document.copyPage()` method.

Or you alternatively prepare a complete new page layout in form of a Python sequence, that contains the page numbers you want, in the sequence you want, and as many times as you want each page. The following may illustrate what can be done with `Document.select()`:

```
doc.select([1, 1, 1, 5, 4, 9, 9, 9, 0, 2, 2, 2])
```

Now let’s prepare a PDF for double-sided printing (on a printer not directly supporting this):

The number of pages is given by `len(doc)` (equal to `doc.page_count`). The following lists represent the even and the odd page numbers, respectively:

```
>>> p_even = [p in range(len(doc)) if p % 2 == 0]
>>> p_odd = [p in range(len(doc)) if p % 2 == 1]
```

This snippet creates the respective sub documents which can then be used to print the document:

```
>>> doc.select(p_even)  # only the even pages left over
>>> doc.save("even.pdf")  # save the "even" PDF
>>> doc.close()  # recycle the file
>>> doc = fitz.open(doc.name)  # re-open
>>> doc.select(p_odd)  # and do the same with the odd pages
>>> doc.save("odd.pdf")
```

For more information also have a look at this Wiki article.

The following example will reverse the order of all pages (**extremely fast**: sub-second time for the 1310 pages of the Adobe PDF References):

```
>>> lastPage = len(doc) - 1
>>> for i in range(lastPage):
...     doc.movePage(lastPage, i)  # move current last page to the front
```

This snippet duplicates the PDF with itself so that it will contain the pages 0, 1, …, n, 0, 1, …, n (**extremely fast and without noticeably increasing the file size!**):

```
>>> page_count = len(doc)
>>> for i in range(page_count):
...     doc.copyPage(i)  # copy this page to after last page
```
4.7.4 How to Join PDFs

It is easy to join PDFs with method `Document.insert_pdf()`. Given open PDF documents, you can copy page ranges from one to the other. You can select the point where the copied pages should be placed, you can revert the page sequence and also change page rotation. This Wiki article contains a full description.

The GUI script `PDFjoiner.py` uses this method to join a list of files while also joining the respective table of contents segments. It looks like this:

![PDF joiner GUI screenshot](image)

4.7.5 How to Add Pages

There two methods for adding new pages to a PDF: `Document.insert_page()` and `Document.new_page()` (and they share a common code base).

`new_page`

`Document.new_page()` returns the created `Page` object. Here is the constructor showing defaults:

```python
>>> doc = fitz.open(...)  # some new or existing PDF document
>>> page = doc.new_page(to = -1,  # insertion point: end of document
                      width = 595,  # page dimension: A4 portrait
                      height = 842)
```

The above could also have been achieved with the short form `page = doc.new_page()`. The `to` parameter specifies the document’s page number (0-based) in front of which to insert.

To create a page in `landscape` format, just exchange the width and height values.
Use this to create the page with another pre-defined paper format:

```python
>>> w, h = fitz.PaperSize("letter-l")  # 'Letter' landscape
>>> page = doc.new_page(width = w, height = h)
```

The convenience function `PaperSize()` knows over 40 industry standard paper formats to choose from. To see them, inspect dictionary `paperSizes`. Pass the desired dictionary key to `PaperSize()` to retrieve the paper dimensions. Upper and lower case is supported. If you append “-L” to the format name, the landscape version is returned.

Note: Here is a 3-liner that creates a PDF with one empty page. Its file size is 470 bytes:

```python
>>> doc = fitz.open()
>>> doc.new_page()
>>> doc.save("A4.pdf")
```

`insert_page`

`Document.insert_page()` also inserts a new page and accepts the same parameters `to`, `width` and `height`. But it lets you also insert arbitrary text into the new page and returns the number of inserted lines:

```python
>>> doc = fitz.open(...)  # some new or existing PDF document
>>> n = doc.insert_page(to = -1,  # default insertion point
                      text = None,  # string or sequence of strings
                      fontsize = 11,
                      width = 595,
                      height = 842,
                      fontname = "Helvetica",  # default font
                      fontfile = None,  # any font file name
                      color = (0, 0, 0))  # text color (RGB)
```

The text parameter can be a (sequence of) string (assuming UTF-8 encoding). Insertion will start at `Point` (50, 72), which is one inch below top of page and 50 points from the left. The number of inserted text lines is returned. See the method definition for more details.

## 4.7.6 How To Dynamically Clean Up Corrupt PDFs

This shows a potential use of PyMuPDF with another Python PDF library (the excellent pure Python package `pdfrw` is used here as an example).

If a clean, non-corrupt / decompressed PDF is needed, one could dynamically invoke PyMuPDF to recover from many problems like so:

```python
import sys
from io import BytesIO
from pdfrw import PdfReader
import fitz

#---------------------------------------
# 'Tolerant' PDF reader
#---------------------------------------

def reader(fname, password = None):
    idata = open(fname, "rb").read()  # read the PDF into memory and
```

(continues on next page)
ibuffer = BytesIO(idata)  # convert to stream
if password is None:
    try:
        return PdfReader(ibuffer)  # if this works: fine!
    except:
        pass

# either we need a password or it is a problem-PDF
# create a repaired / decompressed / decrypted version
doc = fitz.open("pdf", ibuffer)
if password is not None:  # decrypt if password provided
    rc = doc.authenticate(password)
    if not rc > 0:
        raise ValueError("wrong password")
c = doc.tobytes(garbage=3, deflate=True)
del doc  # close & delete doc
return PdfReader(BytesIO(c))  # let pdfrw retry

#---------------------------------------
# Main program
#---------------------------------------

With the command line utility pdfkit (available for Windows only, but reported to also run under Wine) a similar result can be achieved, see here. However, you must invoke it as a separate process via subprocess.Popen, using stdin and stdout as communication vehicles.

### 4.7.7 How to Split Single Pages

This deals with splitting up pages of a PDF in arbitrary pieces. For example, you may have a PDF with Letter format pages which you want to print with a magnification factor of four: each page is split up in 4 pieces which each go to a separate PDF page in Letter format again:

```
###
Create a PDF copy with split-up pages (posterize)
---------------------------------------------
License: GNU GPL V3
(c) 2018 Jorj X. McKie

Usage
------
python posterize.py input.pdf

Result
------
A file "poster-input.pdf" with 4 output pages for every input page.

Notes
-----
(1) Output file is chosen to have page dimensions of 1/4 of input.
(2) Easily adapt the example to make n pages per input, or decide per each input page or whatever.
```

(continues on next page)
from __future__ import print_function
import fitz, sys

infile = sys.argv[1]  # input file name
src = fitz.open(infile)
doc = fitz.open()  # empty output PDF

for spage in src:  # for each page in input
    r = spage.rect  # input page rectangle
    d = fitz.Rect(spage.CropBoxPosition,  # CropBox displacement if not
                  spage.CropBoxPosition)  # starting at (0, 0)

    # example: cut input page into 2 x 2 parts
    r1 = r / 2  # top left rect
    r2 = r1 + (r1.width, 0, r1.width, 0)  # top right rect
    r3 = r1 + (0, r1.height, 0, r1.height)  # bottom left rect
    r4 = fitz.Rect(r1.br, r.br)  # bottom right rect
    rect_list = [r1, r2, r3, r4]  # put them in a list

    for rx in rect_list:  # run thru rect list
        rx += d  # add the CropBox displacement
        page = doc.new_page(-1,  # new output page with rx dimensions
                            width=rx.width,
                            height=rx.height)
        page.show_pdf_page(
            page.rect,  # fill all new page with the image
            src,  # input document
            spage.number,  # input page number
            clip=rx,  # which part to use of input page
        )

    # that's it, save output file
    doc.save("poster-" + src.name,
             garbage=3,  # eliminate duplicate objects
deflate=True,  # compress stuff where possible)

This shows what happens to an input page:
4.7.8 How to Combine Single Pages

This deals with joining PDF pages to form a new PDF with pages each combining two or four original ones (also called “2-up”, “4-up”, etc.). This could be used to create booklets or thumbnail-like overviews:

```python
from __future__ import print_function
import fitz, sys

infile = sys.argv[1]
src = fitz.open(infile)
doc = fitz.open() # empty output PDF

width, height = fitz.PaperSize("a4") # A4 portrait output page format
r = fitz.Rect(0, 0, width, height)

# define the 4 rectangles per page
r1 = r / 2 # top left rect
r2 = r1 + (r1.width, 0, r1.width, 0) # top right
r3 = r1 + (0, r1.height, 0, r1.height) # bottom left
r4 = fitz.Rect(r1.br, r.br) # bottom right

r_tab = [r1, r2, r3, r4]

# now copy input pages to output
for spage in src:
    if spage.number % 4 == 0: # create new output page
        page = doc.new_page(-1,
                          width = width,
                          height = height)
        # insert input page into the correct rectangle
        page.show_pdf_page(r_tab[spage.number % 4], # select output rect
```

(continues on next page)
How to Convert Any Document to PDF

Here is a script that converts any PyMuPDF supported document to a PDF. These include XPS, EPUB, FB2, CBZ and all image formats, including multi-page TIFF images.

It features maintaining any metadata, table of contents and links contained in the source document:

```python
from __future__ import print_function

# Demo script: Convert input file to a PDF
# Intended for multi-page input files like XPS, EPUB etc.

Features:
---------
Recovery of table of contents and links of input file.
While this works well for bookmarks (outlines, table of contents),
links will only work if they are not of type "LINK_NAMED".
This link type is skipped by the script.

For XPS and EPUB input, internal links however are of type "LINK_NAMED".
Base library MuPDF does not resolve them to page numbers.

So, for anyone expert enough to know the internal structure of these
document types, can further interpret and resolve these link types.

Dependencies
------------
PyMuPDF v1.14.0+

# import sys
import fitz
if not (list(map(int, fitz.VersionBind.split(".")))) >= [1,14,0]):
    raise SystemExit("need PyMuPDF v1.14.0+")
fn = sys.argv[1]
```

(continues on next page)
print("Converting '%s' to '%s.pdf'" % (fn, fn))

doc = fitz.open(fn)

b = doc.convert_to_pdf()  # convert to pdf
pdf = fitz.open("pdf", b)  # open as pdf

toc = doc.get_toc()  # table of contents of input
pdf.set_toc(toc)  # simply set it for output
meta = doc.metadata  # read and set metadata
if not meta["producer"]:  # "producer"
    meta["producer"] = "PyMuPDF v" + fitz.VersionBind
if not meta["creator"]:  # "creator"
    meta["creator"] = "PyMuPDF PDF converter"
meta["modDate"] = fitz.getPDFnow()
meta["creationDate"] = meta["modDate"]
pdf.set_metadata(meta)

# now process the links
link_cnti = 0
link_skip = 0
for pinput in doc:  # iterate through input pages
    links = pinput.getLinks()  # get list of links
    link_cnti += len(links)  # count how many
    pout = pdf[pinput.number]  # read corresp. output page
    for l in links:  # iterate the links
        if l["kind"] == fitz.LINK_NAMED:  # we do not handle named links
            print("named link page", pinput.number, l)
            link_skip += 1  # count them
            continue
        pout.insertLink(l)  # simply output the others

# save the conversion result
pdf.save(fn + ".pdf", garbage=4, deflate=True)
# say how many named links we skipped
if link_cnti > 0:
    print("Skipped %i named links of a total of %i in input." % (link_skip, link_cnti))

4.7.10 How to Deal with Messages Issued by MuPDF

Since PyMuPDF v1.16.0, **error messages** issued by the underlying MuPDF library are being redirected to the Python standard device `sys.stderr`. So you can handle them like any other output going to this device.

In addition, these messages go to the internal buffer together with any MuPDF warnings — see below.

We always prefix these messages with an identifying string "mupdf:“. If you prefer to not see recoverable MuPDF errors at all, issue the command `fitz.TOOLS.mupdf_display_errors(False)`.

MuPDF warnings continue to be stored in an internal buffer and can be viewed using `Tools.mupdf_warnings()`.

Please note that MuPDF errors may or may not lead to Python exceptions. In other words, you may see error messages from which MuPDF can recover and continue processing.
Example output for a recoverable error. We are opening a damaged PDF, but MuPDF is able to repair it and gives us a few information on what happened. Then we illustrate how to find out whether the document can later be saved incrementally. Checking the Document.isDirty attribute at this point also indicates that the open had to repair the document:

```python
>>> import fitz
>>> doc = fitz.open("damaged-file.pdf")  # leads to a sys.stderr message:
mupdf: cannot find startxref
>>> print(fitz.TOOLS.mupdf_warnings())  # check if there is more info:
cannot find startxref
trying to repair broken xref
repairing PDF document
object missing 'endobj' token
>>> doc.can_save_incremen­tally()  # this is to be expected:
False
>>> # the following indicates whether there are updates so far
>>> # this is the case because of the repair actions:
>>> doc.isDirty
True
>>> # the document has nevertheless been created:
>>> doc
fitz.Document('damaged-file.pdf')
>>> # we now know that any save must occur to a new file
```

Example output for an unrecoverable error:

```python
>>> import fitz
>>> doc = fitz.open("does-not-exist.pdf")
```
mupdf: cannot open does-not-exist.pdf: No such file or directory

```
Traceback (most recent call last):
  File "<pyshell#1>" , line 1, in <module>
    doc = fitz.open("does-not-exist.pdf")
  File "C:\Users\Jorj\AppData\Local\Programs\Python\Python37\lib\site-packages\fitz\fitz.py" , line 2200, in __init__
    _fitz.Document_swiginit(self, _fitz.new_Document(filename, stream, filetype, rect, width, height, fontsize))
RuntimeError: cannot open does-not-exist.pdf: No such file or directory
```

4.7.11 How to Deal with PDF Encryption

Starting with version 1.16.0, PDF decryption and encryption (using passwords) are fully supported. You can do the following:

- Check whether a document is password protected / (still) encrypted (`Document.needsPass`, `Document.is_encrypted`).
- Gain access authorization to a document (`Document.authenticate()`).
- Set encryption details for PDF files using `Document.save()` or `Document.write()` and
  - decrypt or encrypt the content
  - set password(s)
  - set the encryption method
  - set permission details
Note: A PDF document may have two different passwords:

- The **owner password** provides full access rights, including changing passwords, encryption method, or permission detail.
- The **user password** provides access to document content according to the established permission details. If present, opening the PDF in a viewer will require providing it.

Method `Document.authenticate()` will automatically establish access rights according to the password used.

The following snippet creates a new PDF and encrypts it with separate user and owner passwords. Permissions are granted to print, copy and annotate, but no changes are allowed to someone authenticating with the user password:

```python
import fitz

text = "some secret information"  # keep this data secret
perm = int(
    fitz.PDF_PERM_ACCESSIBILITY  # always use this
    | fitz.PDF_PERM_PRINT        # permit printing
    | fitz.PDF_PERM_COPY         # permit copying
    | fitz.PDF_PERM_ANNOTATE     # permit annotations
)
owner_pass = "owner"  # owner password
user_pass = "user"   # user password
encrypt_meth = fitz.PDF_ENCRYPT_AES_256  # strongest algorithm

doc = fitz.open()  # empty pdf
page = doc.new_page()  # empty page
page.insertText((50, 72), text)  # insert the data

doc.save("secret.pdf",
    encryption=encrypt_meth,  # set the encryption method
    owner_pw=owner_pass,  # set the owner password
    user_pw=user_pass,  # set the user password
    permissions=perm,  # set permissions
)
```

Opening this document with some viewer (Nitro Reader 5) reflects these settings:
Decrypting will automatically happen on save as before when no encryption parameters are provided.

To keep the encryption method of a PDF save it using `encryption=fitz.PDF_ENCRYPT_KEEP`. If `doc.can_save_incrementally() == True`, an incremental save is also possible.

To change the encryption method specify the full range of options above (encryption, owner_pw, user_pw, permissions). An incremental save is not possible in this case.

## 4.8 Common Issues and their Solutions

### 4.8.1 Changing Annotations: Unexpected Behaviour

#### 4.8.1.1 Problem

There are two scenarios:

1. **Updating** an annotation with PyMuPDF which was created by some other software.
2. **Creating** an annotation with PyMuPDF and later changing it with some other software.

In both cases you may experience unintended changes, like a different annotation icon or text font, the fill color or line dashing have disappeared, line end symbols have changed their size or even have disappeared too, etc.

#### 4.8.1.2 Cause

Annotation maintenance is handled differently by each PDF maintenance application. Some annotation types may not be supported, or not be supported fully or some details may be handled in a different way than in another application. There is no standard.

Almost always a PDF application also comes with its own icons (file attachments, sticky notes and stamps) and its own set of supported text fonts. For example:
• (Py-) MuPDF only supports these 5 basic fonts for ‘FreeText’ annotations: Helvetica, Times-Roman, Courier, ZapfDingbats and Symbol – no italics / no bold variations. When changing a ‘FreeText’ annotation created by some other app, its font will probably not be recognized nor accepted and be replaced by Helvetica.

• PyMuPDF supports all PDF text markers (highlight, underline, strikeout, squiggly), but these types cannot be updated with Adobe Acrobat Reader.

In most cases there also exists limited support for line dashing which causes existing dashes to be replaced by straight lines. For example:

• PyMuPDF fully supports all line dashing forms, while other viewers only accept a limited subset.

4.8.1.3 Solutions

Unfortunately there is not much you can do in most of these cases.

1. Stay with the same software for creating and changing an annotation.

2. When using PyMuPDF to change an “alien” annotation, try to avoid `Annot.update()`. The following methods can be used without it, so that the original appearance should be maintained:

   • `Annot.set_rect()` (location changes)
   • `Annot.set_flags()` (annotation behaviour)
   • `Annot.set_info()` (meta information, except changes to `content`)
   • `Annot.set_popup()` (create popup or change its rect)
   • `Annot.set_optional_content()` (add / remove reference to optional content information)
   • `Annot.set_open()`
   • `Annot.update_file()` (file attachment changes)

4.8.2 Misplaced Item Insertions on PDF Pages

4.8.2.1 Problem

You inserted an item (like an image, an annotation or some text) on an existing PDF page, but later you find it being placed at a different location than intended. For example an image should be inserted at the top, but it unexpectedly appears near the bottom of the page.

4.8.2.2 Cause

The creator of the PDF has established a non-standard page geometry without keeping it “local” (as they should!). Most commonly, the PDF standard point (0,0) at bottom-left has been changed to the top-left point. So top and bottom are reversed – causing your insertion to be misplaced.

The visible image of a PDF page is controlled by commands coded in a special mini-language. For an overview of this language consult “Operator Summary” on pp. 985 of the Adobe PDF References. These commands are stored in contents objects as strings (`bytes` in PyMuPDF).

There are commands in that language, which change the coordinate system of the page for all the following commands. In order to limit the scope of such commands local, they must be wrapped by the command pair `q` (“save graphics state”), or “stack”) and `Q` (“restore graphics state”, or “unstack”).

So the PDF creator did this:
stream
1 0 0 -1 0 792 cm % change of coordinate system:
... % letter page, top / bottom reversed
... % remains active beyond these lines
endstream

where they should have done this:

stream
q % put the following in a stack
1 0 0 -1 0 792 cm % scope of this is limited by Q command
... % here, a different geometry exists
Q % after this line, geometry of outer scope prevails
endstream

Note:

• In the mini-language’s syntax, spaces and line breaks are equally accepted token delimiters.

• Multiple consecutive delimiters are treated as one.

• Keywords “stream” and “endstream” are inserted automatically – not by the programmer.

4.8.2.3 Solutions

Since v1.16.0, there is the property `Page._isWrapped`, which lets you check whether a page’s contents are wrapped in that string pair.

If it is False or if you want to be on the safe side, pick one of the following:

1. The easiest way: in your script, do a `Page.cleanContents()` before you do your first item insertion.

2. Pre-process your PDF with the MuPDF command line utility `mutool clean -c . . .` and work with its output file instead.

3. Directly wrap the page’s contents with the stacking commands before you do your first item insertion.

**Solutions 1. and 2.** use the same technical basis and do a lot more than what is required in this context: they also clean up other inconsistencies or redundancies that may exist, multiple /Contents objects will be concatenated into one, and much more.

**Note:** For incremental saves, solution 1. has an unpleasant implication: it will bloat the update delta, because it changes so many things and, in addition, stores the **cleaned contents uncompressed**. So, if you use `Page.cleanContents()` you should consider saving to a new file with (at least) garbage=3 and deflate=True.

**Solution 3.** is completely under your control and only does the minimum corrective action. There exists a handy low-level utility function which you can use for this. Suggested procedure:

• **Prepend** the missing stacking command by executing `fitz.TOOLS._insert_contents(page, b"qn", False).

• **Append** an unstacking command by executing `fitz.TOOLS._insert_contents(page, b"nQ", True).

• Alternatively, just use `Page._wrapContents()`, which executes the previous two functions.
Note: If small incremental update deltas are a concern, this approach is the most effective. Other contents objects are not touched. The utility method creates two new PDF stream objects and inserts them before, resp. after the page’s other contents. We therefore recommend the following snippet to get this situation under control:

```python
>>> if not page._isWrapped:
    page._wrapContents()
>>> # start inserting text, images or annotations here
```

4.9 Low-Level Interfaces

Numerous methods are available to access and manipulate PDF files on a fairly low level. Admittedly, a clear distinction between “low level” and “normal” functionality is not always possible or subject to personal taste.

It also may happen, that functionality previously deemed low-level is later on assessed as being part of the normal interface. This has happened in v1.14.0 for the class Tools – you now find it as an item in the Classes chapter.

Anyway – it is a matter of documentation only: in which chapter of the documentation do you find what. Everything is available always and always via the same interface.

4.9.1 How to Iterate through the xref Table

A PDF’s xref table is a list of all objects defined in the file. This table may easily contain many thousand entries – the manual Adobe PDF References for example has over 330’000 objects. Table entry “0” is reserved and must not be touched. The following script loops through the xref table and prints each object’s definition:

```python
>>> xreflen = doc.xref_length()  # length of objects table
>>> for xref in range(1, xreflen):  # skip item 0!
    print("")
    print("object %i (stream: %s)" % (xref, doc.is_stream(xref)))
    print(doc.xref_object(i, compressed=False))
```

This produces the following output:

```
object 1 (stream: False)
<<
   /ModDate (D:20170314122233-04'00')
   /PXCViewerInfo (PDF-XChange Viewer;2.5.312.1;Feb 9 2015;12:00:06;→D:20170314122233-04'00')
>>

object 2 (stream: False)
<<
   /Type /Catalog
   /Pages 3 0 R
>>

object 3 (stream: False)
<<
```

(continues on next page)
A PDF object definition is an ordinary ASCII string.

4.9.2 How to Handle Object Streams

Some object types contain additional data apart from their object definition. Examples are images, fonts, embedded files or commands describing the appearance of a page.

Objects of these types are called “stream objects”. PyMuPDF allows reading an object’s stream via method `Document.xrefStream()` with the object’s `xref` as an argument. And it is also possible to write back a modified version of a stream using `Document.updatefStream()`.

Assume that the following snippet wants to read all streams of a PDF for whatever reason:

```python
>>> xreflen = doc.xref_length()  # number of objects in file
>>> for xref in range(1, xreflen):  # skip item 0!
    if stream := doc.xref_stream(xref):
        # do something with it (it is a bytes object or None)
        # e.g. just write it back:
        doc.update_stream(xref, stream)
```

4.9.3 How to Handle Page Contents

A PDF page can have zero or multiple `contents` objects. These are stream objects describing what appears where on a page (like text and images). They are written in a special mini-language described e.g. in chapter “APPENDIX A - Operator Summary” on page 985 of the *Adobe PDF References*. 
Every PDF reader application must be able to interpret the contents syntax to reproduce the intended appearance of the page.

If multiple contents objects are provided, they must be read and interpreted in the specified sequence in exactly the same way as if these streams were provided as a concatenation of the several.

There are good technical arguments for having multiple contents objects:

- It is a lot easier and faster to just add new contents objects than maintaining a single big one (which entails reading, decompressing, modifying, recompressing, and rewriting it for each change).

- When working with incremental updates, a modified big contents object will bloat the update delta and can thus easily negate the efficiency of incremental saves.

For example, PyMuPDF adds new, small contents objects in methods Page.insert_image(), Page.show_pdf_page() and the Shape methods.

However, there are also situations when a single contents object is beneficial: it is easier to interpret and better compressible than multiple smaller ones.

Here are two ways of combining multiple contents of a page:

```
>>> # method 1: use the clean function
>>> for page in doc:
    page.clean_contents()  # cleans and combines multiple Contents
    xref = page.get_contents()[0]  # only one /Contents now!
    cont = doc.xref_stream(xref)
    # do something with the cleaned, combined contents

>>> # method 2: concatenate multiple contents yourself
>>> for page in doc:
    cont = b""  # initialize contents
    for xref in page.get_contents():  # loop through content xrefs
        cont += doc.xref_stream(xref)
    # do something with the combined contents
```

The clean function Page.clean_contents() does a lot more than just gluing contents objects: it also corrects and optimizes the PDF operator syntax of the page and removes any inconsistencies with the page’s object definition.

### 4.9.4 How to Access the PDF Catalog

This is a central (“root”) object of a PDF. It serves as a starting point to reach important other objects and it also contains some global options for the PDF:

```
>>> import fitz
>>> doc = fitz.open("PyMuPDF.pdf")
>>> cat = doc.pdf_catalog()  # get xref of the /Catalog
>>> print(doc.xref_object(cat))  # print object definition
<<
  /Type/Catalog               % object type
  /Pages 3593 0 R            % points to page tree
  /OpenAction 225 0 R        % action to perform on open
  /Names 3832 0 R            % points to global names tree
  /PageMode /UseOutlines     % initially show the TOC
  /PageLabels<</Nums[0<</S/D>>2<</S/r>>B<</S/D>>]>% labels given to pages
  /Outlines 3835 0 R         % points to outline tree
>>
```
4.9.5 How to Access the PDF File Trailer

The trailer of a PDF file is a dictionary located towards the end of the file. It contains special objects, and pointers to important other information. See Adobe PDF References p. 96. Here is an overview:

<table>
<thead>
<tr>
<th>Key</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Size</td>
<td>int</td>
<td>Number of entries in the cross-reference table + 1.</td>
</tr>
<tr>
<td>Prev</td>
<td>int</td>
<td>Offset to previous xref section (indicates incremental updates).</td>
</tr>
<tr>
<td>Root</td>
<td>dictionary</td>
<td>(indirect) Pointer to the catalog. See previous section.</td>
</tr>
<tr>
<td>Encrypt</td>
<td>dictionary</td>
<td>Pointer to encryption object (encrypted files only).</td>
</tr>
<tr>
<td>Info</td>
<td>dictionary</td>
<td>(indirect) Pointer to information (metadata).</td>
</tr>
<tr>
<td>ID</td>
<td>array</td>
<td>File identifier consisting of two byte strings.</td>
</tr>
<tr>
<td>XRefStm</td>
<td>int</td>
<td>Offset of a cross-reference stream. See Adobe PDF References p. 109.</td>
</tr>
</tbody>
</table>

Access this information via PyMuPDF with `Document.pdf_trailer()`.

```python
>>> import fitz
>>> doc=fitz.open("PyMuPDF.pdf")
>>> print(doc.pdf_trailer())
<<
/Type /XRef
/Index [ 0 8263 ]
/Size 8263
/W [ 1 3 1 ]
/Root 8260 0 R
/Info 8261 0 R
/ID [ <4339B9CEE46C2CD28A79EBDDD67CC9B3> <4339B9CEE46C2CD28A79EBDDD67CC9B3> ]
/Length 19883
/Filter /FlateDecode
>>
>>>
```

4.9.6 How to Access XML Metadata

A PDF may contain XML metadata in addition to the standard metadata format. In fact, most PDF viewer or modification software adds this type of information when saving the PDF (Adobe, Nitro PDF, PDF-XChange, etc.).

PyMuPDF has no way to interpret or change this information directly, because it contains no XML features. XML metadata is however stored as a stream object, so it can be read, modified with appropriate software and written back.

```python
>>> xmlmetadata = doc.get_xml_metadata()
>>> print(xmlmetadata)
<?xpacket begin="\ufeff" id="W5M0MpCehiHzreSzNTczkc9d"?>
```

(continues on next page)
Using some XML package, the XML data can be interpreted and / or modified and then stored back. The following also works, if the PDF previously had no XML metadata:

```python
>>> # write back modified XML metadata:
>>> doc.set_xml_metadata(xmlmetadata)

>>> # XML metadata can be deleted like this:
>>> doc.del_xml_metadata()
```

### 4.9.7 How to Read and Update PDF Objects

There also exist granular, elegant ways to access and manipulate selected PDF dictionary keys.

- **Document.xref_get_keys()** returns the PDF keys of the object at `xref`:

```python
In [1]: import fitz
In [2]: doc = fitz.open("pymupdf.pdf")
In [3]: page = doc[0]
In [4]: from pprint import pprint
In [5]: pprint(doc.xref_get_keys(page.xref))

('Type', 'Contents', 'Resources', 'MediaBox', 'Parent')
```

- Compare with the full object definition:

```python
In [6]: print(doc.xref_object(page.xref))
<<
/Type /Page
/Contents 1297 0 R
/Resources 1296 0 R
/MediaBox [ 0 0 612 792 ]
/Parent 1301 0 R
>>
```

- Single keys can also be accessed directly via `Document.xref_get_key()`. The value always is a string together with type information, that helps interpreting it:

```python
In [7]: doc.xref_get_key(page.xref, "MediaBox")
Out[7]: ('array', '[0 0 612 792]')
```

- Here is a full listing of the above page keys:

```python
In [9]: for key in doc.xref_get_keys(page.xref):
    ...:     print("%s = %s" % (key, doc.xref_get_key(page.xref, key)))
    ...
Type = ('name', '/Page')
Contents = ('xref', '1297 0 R')
```

(continues on next page)
• An undefined key inquiry returns ('null', 'null') – PDF object type null corresponds to None in Python. Similar for the booleans true and false.

• Let us add a new key to the page definition that sets its rotation to 90 degrees (you are aware that there actually exists `Page.set_rotation()` for this?):

```python
In [11]: doc.xref_get_key(page.xref, "Rotate")  # no rotation set:
Out[11]: ('null', 'null')
In [12]: doc.xref_set_key(page.xref, "Rotate", "90")  # insert a new key
In [13]: print(doc.xref_object(page.xref))  # confirm success
```

```
<<
/Type /Page
/Contents 1297 0 R
/Resources 1296 0 R
/MediaBox [ 0 0 612 792 ]
/Parent 1301 0 R
/Rotate 90
>>
```

• This method can also be used to remove a key from the xref dictionary by setting its value to null: The following will remove the rotation specification from the page: `doc.xref_set_key(page.xref, "Rotate", "null")`. Similarly, to remove all links, annotations and fields from a page, use `doc.xref_set_key(page.xref, "Annots", "null")`. Because Annots by definition is an array, setting an empty array with the statement `doc.xref_set_key(page.xref, "Annots", "[]")` would do the same job in this case.

• PDF dictionaries can be hierarchically nested. In the following page object definition both, Font and XObject are subdictionaries of Resources:

```python
In [15]: print(doc.xref_object(page.xref))
```

```
<<
/Type /Page
/Contents 1297 0 R
/Resources <<
  /XObject <<
    /Im1 1291 0 R
  >/Font <<
    /F39 1299 0 R
    /F40 1300 0 R
  >>
 >>
/MediaBox [ 0 0 612 792 ]
/Parent 1301 0 R
/Rotate 90
>>
```

• The above situation is supported by methods `Document.xref_set_key()` and `Document.xref_get_key()`: use a path-like notation to point at the required key. For example, to retrieve the value of key Im1 above, specify the complete chain of dictionaries “above” it in the key argument: "Resources/XObject/Im1":

```
Resources = ('xref', '1296 0 R')
MediaBox = ('array', '[0 0 612 792]')
Parent = ('xref', '1301 0 R')
```
In [16]: doc.xref_get_key(page.xref, "Resources/XObject/Im1")
Out[16]: ('xref', '1291 0 R')

- The path notation can also be used to **directly set a value**: use the following to let Im1 point to a different object:

In [17]: doc.xref_set_key(page.xref, "Resources/XObject/Im1", "9999 0 R")
In [18]: print(doc.xref_object(page.xref))  # confirm success:
<<
/Type /Page
/Contents 1297 0 R
/Resources <<
/XObject <<
/Im1 9999 0 R
>>
/Font <<
/F39 1299 0 R
/F40 1300 0 R
>>
>>
/Parent 1301 0 R
/Rotate 90
>>

Be aware, that **no semantic checks** whatsoever will take place here: if the PDF has no xref 9999, it won’t be detected at this point.

- If a key does not exist, it will be created by setting its value. Moreover, if any intermediate keys do not exist either, they will also be created as necessary. The following creates an array D several levels below the existing dictionary A. Intermediate dictionaries B and C are automatically created:

In [5]: print(doc.xref_object(xref))  # some existing PDF object:
<<
/A <<
>>
>>
In [6]: # the following will create 'B', 'C' and 'D'
In [7]: doc.xref_set_key(xref, "A/B/C/D", "[1 2 3 4]")
In [8]: print(doc.xref_object(xref))  # check out what happened:
<<
/A <<
/B <<
/C <<
/D [ 1 2 3 4 ]
>>
>>
>>

- When setting key values, basic PDF **syntax checking** will be done by MuPDF. For example, new keys can only be created **below a dictionary**. The following tries to create some new string item E below the previously created array D:

In [9]: # 'D' is an array, no dictionary!
In [10]: doc.xref_set_key(xref, "A/B/C/D/E", "(hello)")
mupdf: not a dict (array)

(continues on next page)
• It is also **not possible**, to create a key if some higher level key is an “**indirect**” object, i.e. an xref. In other words, xrefs can only be modified directly and not implicitly via other objects referencing them:

```python
In [13]: # the following object points to an xref
In [14]: print(doc.xref_object(4))
<<
  /E 3 0 R
>>
In [15]: # 'E' is an indirect object and cannot be modified here!
In [16]: doc.xref_set_key(4, "E/F", "90")
mupdf: path to 'F' has indirects
```

**Caution:** These are expert functions! There are no validations as to whether valid PDF objects, xrefs, etc. are specified. As with other low-level methods there exists the risk to render the PDF, or parts of it unusable.
PyMuPDF can also be used in the command line as a module to perform basic utility functions. This is work in progress and subject to changes. This feature should obsolete writing some of the most basic scripts. As a guideline we are using the feature set of MuPDF command line tools. Admittedly, there is some functional overlap. On the other hand, PDF embedded files are no longer supported by MuPDF, so PyMuPDF is offering something unique here.

5.1 Invocation

Invoke the module like this:

```
python -m fitz command parameters
```

General remarks:

- Request help via “-h”, resp. command-specific help via “command -h”.
- Parameters may be abbreviated as long as the result is not ambiguous (Python 3.5 or later only).
- Several commands support parameters -pages and -xrefs. They are intended for down-selection. Please note that:
  - **page numbers** for this utility must be given 1-based.
  - valid **xref** numbers start at 1.
  - Specify any number of either single integers or integer ranges, separated by one comma each. A range is a pair of integers separated by one hyphen “-“. Integers must not exceed the maximum page number or resp. **xref** number. To specify that maximum, the symbolic variable “N” may be used instead of an integer. Integers or ranges may occur several times, in any sequence and may overlap. If in a range the first number is greater than the second one, the respective items will be processed in reversed order.
- You can also use the fitz module inside your script:
>>> from fitz.__main__ import main as fitz_command
>>> cmd = "clean input.pdf output.pdf -pages 1,N".split() # prepare command
>>> saved_parms = sys.argv[1:] # save original parameters
>>> sys.argv[1:] = cmd # store command
>>> fitz_command() # execute command
>>> sys.argv[1:] = saved_parms # restore original parameters

- You can use the following 2-liner and compile it with Nuitka in either normal or standalone mode, if you want to distribute it. This will give you a command line utility with all the functions explained below:

```python
from fitz.__main__ import main
main()
```

## 5.2 Cleaning and Copying

This command will optimize the PDF and store the result in a new file. You can use it also for encryption, decryption and creating sub documents. It is mostly similar to the MuPDF command line utility “mutool clean”:

```
python -m fitz clean -h
input output
```

```
-------------- optimize PDF or create sub-PDF if pages given --------------
```

**Positional arguments:**
- `input` PDF filename
- `output` output PDF filename

**Optional arguments:**
- `-h, --help` show this help message and exit
- `-password PASSWORD` password
- `-encryption {keep,none,rc4-40,rc4-128,aes-128,aes-256}` encryption method
- `-owner OWNER` owner password
- `-user USER` user password
- `-garbage {0,1,2,3,4}` garbage collection level
- `-compress` compress (deflate) output
- `-ascii` ASCII encode binary data
- `-linear` format for fast web display
- `-permission PERMISSION` integer with permission levels
- `-sanitize` sanitize / clean contents
- `-pretty` prettyfy PDF structure
- `-pages PAGES` output selected pages, format: 1,5-7,50-N

If you specify “-pages”, be aware that only page-related objects are copied, no document-level items like e.g. embedded files.

Please consult `Document.save()` for the parameter meanings.
5.3 Extracting Fonts and Images

Extract fonts or images from selected PDF pages to a desired directory:

```python
python -m fitz extract -h
            [-pages PAGES] input

--------------------- extract images and fonts to disk ---------------------

positional arguments:
input	PDF filename

optional arguments:
-h, --help	show this help message and exit
-images	extract images
-fonts	extract fonts
-output OUTPUT	output directory, defaults to current
-password PASSWORD	password
-pages PAGES	only consider these pages, format: 1,5-7,50-N
```

Image filenames are built according to the naming scheme: “img-xref.ext”, where “ext” is the extension associated with the image and “xref” the xref of the image PDF object.

Font filenames consist of the fontname and the associated extension. Any spaces in the fontname are replaced with hyphens “-“.

The output directory must already exist.

---

**Note:** Except for output directory creation, this feature is functionally equivalent to and obsoletes this script.

5.4 Joining PDF Documents

To join several PDF files specify:

```python
python -m fitz join -h
usage: fitz join [-h] -output OUTPUT [input [input ...]]

------------------------------------- join PDF documents -------------------------------------

positional arguments:
input	input filenames

optional arguments:
-h, --help	show this help message and exit
-output OUTPUT	output filename

specify each input as 'filename[,password[,pages]]'
```

**Note:**
1. Each input must be entered as “filename,password,pages”. Password and pages are optional.
2. The password entry is required if the “pages” entry is used. If the PDF needs no password, specify two commas.

3. The “pages” format is the same as explained at the top of this section.

4. Each input file is immediately closed after use. Therefore you can use one of them as output filename, and thus overwrite it.

Example: To join the following files

1. file1.pdf: all pages, back to front, no password
2. file2.pdf: last page, first page, password: “secret”
3. file3.pdf: pages 5 to last, no password

and store the result as output.pdf enter this command:

```
python -m fitz join -o output.pdf file1.pdf"N-1 file2.pdf,secret,N,1 file3.pdf.,5-N
```

5.5 Low Level Information

Display PDF internal information. Again, there are similarities to “mutool show”:

```
python -m fitz show -h
usage: fitz show [-h] [-password PASSWORD] [-catalog] [-trailer] [-metadata]
     [-xrefs XREFS] [-pages PAGES]
input

------------------------- display PDF information -------------------------

positional arguments:
input          PDF filename

optional arguments:
-h, --help      show this help message and exit
-password PASSWORD  password
-catalog        show PDF catalog
-trailer        show PDF trailer
-metadata        show PDF metadata
-xrefs XREFS    show selected objects, format: 1,5-7,N
-pages PAGES   show selected pages, format: 1,5-7,50-N
```

Examples:

```
python -m fitz show x.pdf
PDF is password protected

python -m fitz show x.pdf -pass hugo
authentication unsuccessful

python -m fitz show x.pdf -pass jorjmckie
authenticated as owner
file 'x.pdf', pages: 1, objects: 19, 58 MB, PDF 1.4, encryption: Standard V5 R6 256-
→bit AES
Document contains 15 embedded files.

python -m fitz show FDA-1572_508_R6_FINAL.pdf -tr -m
```
5.6 Embedded Files Commands

The following commands deal with embedded files – which is a feature completely removed from MuPDF after v1.14, and hence from all its command line tools.

5.6.1 Information

Show the embedded file names (long or short format):

```
python -m fitz embed-info -h
```

-------------------- list embedded files --------------------

positional arguments:
input PDF filename

optional arguments:
-h, --help show this help message and exit
-name NAME if given, report only this one
-detail show detail information
-password PASSWORD password

Example:

```python
python -m fitz embed-info some.pdf
'some.pdf' contains the following 15 embedded files.

20110813_180956_0002.jpg
20110813_181009_0003.jpg
20110813_181012_0004.jpg
20110813_181131_0005.jpg
20110813_181144_0006.jpg
20110813_181306_0007.jpg
20110813_181307_0008.jpg
20110813_181314_0009.jpg
20110813_181315_0010.jpg
20110813_181324_0011.jpg
20110813_181339_0012.jpg
20110813_181913_0013.jpg
insta-20110813_180944_0001.jpg
markiert-20110813_180944_0001.jpg
neue.datei
```

Detailed output would look like this per entry:

```python
name: neue.datei
filename: text-tester.pdf
ufilename: text-tester.pdf
desc: nur zum Testen!
size: 4639
length: 1566
```

### 5.6.2 Extraction

Extract an embedded file like this:

```python
python -m fitz embed-extract -h
usage: fitz embed-extract [-h] -name NAME [-password PASSWORD] [-output OUTPUT] 
    input

---------------------- extract embedded file to disk ----------------------

positional arguments:
    input       PDF filename

optional arguments:
    -h, --help  show this help message and exit
    -name NAME  name of entry
    -password PASSWORD password
    -output OUTPUT output filename, default is stored name
```

For details consult `Document.embfile_get()`. Example (refer to previous section):
5.6.3 Deletion

Delete an embedded file like this:

```
python -m fitz embed-del -h
usage: fitz embed-del [-h] [-password PASSWORD] [-output OUTPUT] -name NAME input

--------------------------- delete embedded file --------------------------

positional arguments:
input  PDF filename

optional arguments:
-h, --help  show this help message and exit
-password PASSWORD  password
-output OUTPUT  output PDF filename, incremental save if none
-name NAME  name of entry to delete
```

For details consult `Document.embfile_del()`.

5.6.4 Insertion

Add a new embedded file using this command:

```
python -m fitz embed-add -h

input

--------------------------- add embedded file --------------------------

positional arguments:
input  PDF filename

optional arguments:
-h, --help  show this help message and exit
-password PASSWORD  password
-output OUTPUT  output PDF filename, incremental save if none
-name NAME  name of new entry
-path PATH  path to data for new entry
-desc DESC  description of new entry
```

“NAME” must not already exist in the PDF. For details consult `Document.embfile_add()`.

5.6.5 Updates

Update an existing embedded file using this command:
### 5.6.6 Copying

Copy embedded files between PDFs:

```python
python -m fitz embed-copy -h
input

-------------------- copy embedded files between PDFs ---------------------
```

**position arguments:**
- PDF to receive embedded files

**optional arguments:**
- `-h, --help` show this help message and exit
- `-password PASSWORD` password of input
- `-output OUTPUT` output PDF, incremental save to 'input' if omitted
- `-source SOURCE` copy embedded files from here
- `-pwdsource PWDSOURCE` password of 'source' PDF
- `-name [NAME [NAME ...]]` restrict copy to these entries

Use this method to change meta-information of the file – just omit the “PATH”. For details consult Document. `embfile_upd()`.
6.1 Annot

This class is supported for PDF documents only.

Quote from the Adobe PDF References: “An annotation associates an object such as a note, sound, or movie with a location on a page of a PDF document, or provides a way to interact with the user by means of the mouse and keyboard.”

There is a parent-child relationship between an annotation and its page. If the page object becomes unusable (closed document, any document structure change, etc.), then so does every of its existing annotation objects – an exception is raised saying that the object is “orphaned”, whenever an annotation property or method is accessed.

Note: Unfortunately, there exists no single, unique naming convention in PyMuPDF: examples for all of CamelCases, mixedCases and lower_case_with_underscores can be found all over the place. We are now in the process of cleaning this up, step by step.

This class, Annot, is the first candidate for this exercise. In this chapter, you will for example find Annot.get_pixmap() – and no longer the old name getPixmap. The method with the old name however continues to exist and you can continue using it: your existing code will not break. But we do hope you will start using the new names – for new code at least.

### Class API

class Annot

```python
get_pixmap(matrix=fitz.Identity, colorspace=fitz.csRGB, alpha=False)
```

Creates a pixmap from the annotation as it appears on the page in untransformed coordinates. The pixmap’s $IRect$ equals `Annot.rect.irect` (see below). **All parameters are keyword only.**

**Parameters**

- `matrix (matrix_like)` – a matrix to be used for image creation. Default is the `fitz.Identity` matrix.

- `colorspace (Colorspace)` – a colorspace to be used for image creation. Default is `fitz.csRGB`.

- `alpha (bool)` – whether to include transparency information. Default is `False`.

**Return type** `Pixmap`

**Note:** If the annotation has just been created or modified, you should reload the page first via `page =`
get_text (opt, clip=None, flags=None)  
(New in 1.18.0)

Retrieves the content of the annotation in a variety of formats – much like the same method for Page. This currently only delivers relevant data for annotation types ‘FreeText’ and ‘Stamp’. Other types return an empty string (or equivalent objects).

Parameters

- **opt** (str) – (positional only) the desired format - one of the following values. Please note that this method works exactly like the same-named method of Page.
  - "text" – TextPage.extractTEXT(), default
  - "blocks" – TextPage.extractBLOCKS()
  - "words" – TextPage.extractWORDS()
  - "html" – TextPage.extractHTML()
  - "xhtml" – TextPage.extractXHTML()
  - "xml" – TextPage.extractXML()
  - "dict" – TextPage.extractDICT()
  - "json" – TextPage.extractJSON()
  - "rawdict" – TextPage.extractRAWDICT()

- **clip** (rect-like) – (keyword only) restrict the extraction to this area. Should hardly ever be required, defaults to Annot.rect.

- **flags** (int) – (keyword only) control the amount of data returned. Defaults to simple text extraction.

get_textbox (rect)  
(New in 1.18.0)

Return the annotation text. Mostly (except line breaks) equal to Annot.get_text() with the “text” option.

Parameters **rect** (rect-like) – the area to consider, defaults to Annot.rect.

set_info (info=None, content=None, title=None, creationDate=None, modDate=None, subject=None)  
(Changed in version 1.16.10)

Changes annotation properties. These include dates, contents, subject and author (title). Changes for name and id will be ignored. The update happens selectively: To leave a property unchanged, set it to None. To delete existing data, use an empty string.

Parameters

- **info** (dict) – a dictionary compatible with the info property (see below). All entries must be strings. If this argument is not a dictionary, the other arguments are used instead – else they are ignored.

- **content** (str) – (new in v1.16.10) see description in info.

- **title** (str) – (new in v1.16.10) see description in info.

- **creationDate** (str) – (new in v1.16.10) date of annot creation. If given, should be in PDF datetime format.
• **modDate** *(str)* *(new in v1.16.10)* date of last modification. If given, should be in PDF datetime format.

• **subject** *(str)* *(new in v1.16.10)* see description in info.

**set_line_ends**(start, end)
Sets an annotation’s line ending styles. Each of these annotation types is defined by a list of points which are connected by lines. The symbol identified by **start** is attached to the first point, and **end** to the last point of this list. For unsupported annotation types, a no-operation with a warning message results.

**Note:**

• While ‘FreeText’, ‘Line’, ‘PolyLine’, and ‘Polygon’ annotations can have these properties, (Py-) MuPDF does not support line ends for ‘FreeText’, because the call-out variant of it is not supported.

• *(Changed in v1.16.16)* Some symbols have an interior area (diamonds, circles, squares, etc.). By default, these areas are filled with the fill color of the annotation. If this is **None**, then white is chosen. The **fill_color** argument of **Annot.update()** can now be used to override this and give line end symbols their own fill color.

**Parameters**

• **start** *(int)* – The symbol number for the first point.

• **end** *(int)* – The symbol number for the last point.

**set_oc**(xref)
Set the annotation’s visibility using PDF optional content mechanisms. This visibility is controlled by the user interface of supporting PDF viewers. It is independent from other attributes like **Annot.flags**.

**Parameters** **xref** *(int)* – the **xref** of an optional contents group (OCG or OCMD). Any previous xref will be overwritten. If zero, a previous entry will be removed. An exception occurs if the xref is not zero and does not point to a valid PDF object.

**Note:** This does **not require executing** **Annot.update()** to take effect.

**get_oc**()
Return the **xref** of an optional content object, or zero if there is none.

**Returns**  zero or the xref of an OCG (or OCMD).

**set_open**(value)
*(New in v1.18.4)*
Set the annotation’s Popup annotation to open or closed – or the annotation itself, if its type is ‘Text’ (“sticky note”).

**Parameters** **value** *(bool)* – the desired open state.

**set_popup**(rect)
*(New in v1.18.4)*
Create a Popup annotation for the annotation and specify its rectangle. If the Popup already exists, only its rectangle is updated.

**Parameters** **rect** *(rect_like)* – the desired rectangle.

**set_opacity**(value)
Set the annotation’s transparency. Opacity can also be set in **Annot.update()**.
Parameters value (float) – a float in range [0, 1]. Any value outside is assumed to be 1. E.g. a value of 0.5 sets the transparency to 50%.

Three overlapping ‘Circle’ annotations with each opacity set to 0.5:

[Image of three overlapping circles with different opacities]

blendmode

(New in v1.18.4)

The annotation’s blend mode. See Adobe PDF References, page 520 for explanations.

Return type str

Returns the blend mode or None.

```python
>>> annot=page.firstAnnot
>>> annot.blendmode
'Multiply'
```

set_blendmode (blendmode)

(New in v1.16.14) Set the annotation’s blend mode. See Adobe PDF References, page 520 for explanations. The blend mode can also be set in Annot.update().

Parameters blendmode (str) – set the blend mode. Use Annot.update() to reflect this in the visual appearance. For predefined values see PDF Standard Blend Modes. Use PDF_BM_Normal to remove a blend mode.

```python
>>> annot.set_blendmode(fitz.PDF_BM_Multiply)
>>> annot.update()
>>> # or in one statement:
>>> annot.update(blend_mode=fitz.PDF_BM_Multiply, ...)
```

set_name (name)

(New in version 1.16.0) Change the name field of any annotation type. For ‘FileAttachment’ and ‘Text’ annotations, this is the icon name, for ‘Stamp’ annotations the text in the stamp. The visual result (if any) depends on your PDF viewer. See also Annotation Icons in MuPDF.

Parameters name (str) – the new name.

Caution: If you set the name of a ‘Stamp’ annotation, then this will not change the rectangle, nor will the text be layouted in any way. If you choose a standard text from Stamp Annotation Icons (the exact name piece after “STAMP_”), you should receive the original layout. An arbitrary text will not be
set_rect (rect)
Change the rectangle of an annotation. The annotation can be moved around and both sides of the rectangle can be independently scaled. However, the annotation appearance will never get rotated, flipped or sheared.

Parameters rect (rect_like) – the new rectangle of the annotation (finite and not empty).
E.g. using a value of annot.rect + (5, 5, 5, 5) will shift the annot position 5 pixels to the right and downwards.

Note: You need not invoke Annot.update() for activation of the effect.

set_rotation (angle)
Set the rotation of an annotation. This rotates the annotation rectangle around its center point. Then a new annotation rectangle is calculated from the resulting quad.

Parameters angle (int) – rotation angle in degrees. Arbitrary values are possible, but will be clamped to the interval 0 <= angle < 360.

Note:
• You must invoke Annot.update() to activate the effect.
• For PDF_ANNOT_FREE_TEXT, only one of the values 0, 90, 180 and 270 is possible and will rotate the text inside the current rectangle (which remains unchanged). Other values are silently ignored and replaced by 0.
• Otherwise, only the following Annotation Types can be rotated: ‘Square’, ‘Circle’, ‘Caret’, ‘Text’, ‘FileAttachment’, ‘Ink’, ‘Line’, ‘Polyline’, ‘Polygon’, and ‘Stamp’. For all others the method is a no-op.

set_border (border=None, width=0, style=None, dashes=None)
PDF only: Change border width and dashing properties.

Changed in version 1.16.9: Allow specification without using a dictionary. The direct parameters are used if border is not a dictionary.

Parameters
• border (dict) – a dictionary as returned by the border property, with keys “width” (float), “style” (str) and “dashes” (sequence). Omitted keys will leave the resp. property unchanged. To e.g. remove dashing use: “dashes”: []. If dashes is not an empty sequence, “style” will automatically be set to “D” (dashed).
• width (float) – see above.
• style (str) – see above.
• dashes (sequence) – see above.

set_flags (flags)
Changes the annotation flags. Use the | operator to combine several.

Parameters flags (int) – an integer specifying the required flags.
**set_colors** *(colors=None, stroke=None, fill=None)*
Changes the “stroke” and “fill” colors for supported annotation types – not all annotations accept both.

*Changed in version 1.16.9:* Allow colors to be directly set. These parameters are used if *colors* is not a dictionary.

**Parameters**

- **colors** *(dict)* – a dictionary containing color specifications. For accepted dictionary keys and values see below. The most practical way should be to first make a copy of the *colors* property and then modify this dictionary as required.
- **stroke** *(sequence)* – see above.
- **fill** *(sequence)* – see above.

*Changed in v1.18.5:* To completely remove a color specification, use an empty sequence like `[ ]`.

**delete_responses** *
*(New in version 1.16.12)* Delete annotations referring to this one. This includes any ‘Popup’ annotations and all annotations responding to it.

**update** *(opacity=None, blend_mode=None, fontsize=0, text_color=None, border_color=None, fill_color=None, cross_out=True, rotate=-1)*
Synchronize the appearance of an annotation with its properties after any changes.

You can safely omit this method only for the following changes:

- **set_rect**()
- **set_flags**()
- **set_oc**()
- **update_file**()
- **set_info**() (except any changes to “content”)

All arguments are optional. *(Changed in v1.16.14)* Blend mode and opacity are applicable to all annotation types. The other arguments are mostly special use, as described below.

Color specifications may be made in the usual format used in PuMuPDF as sequences of floats ranging from 0.0 to 1.0 (including both). The sequence length must be 1, 3 or 4 (supporting GRAY, RGB and CMYK colorspace respectively). For mono-color, just a float is also acceptable and yields some shade of gray.

**Parameters**

- **opacity** *(float)* – *(new in v1.16.14)* valid for all annotation types: change or set the annotation’s transparency. Valid values are $0 \leq \text{opacity} < 1$.
- **blend_mode** *(str)* – *(new in v1.16.14)* valid for all annotation types: change or set the annotation’s blend mode. For valid values see *PDF Standard Blend Modes*.
- **fontsize** *(float)* – change font size of the text. ‘FreeText’ annotations only.
- **text_color** *(sequence, float)* – change the text color. ‘FreeText’ annotations only.
- **border_color** *(sequence, float)* – change the border color. ‘FreeText’ annotations only.
- **fill_color** *(sequence, float)* – the fill color.
  - ‘Line’, ‘Polyline’, ‘Polygon’ annotations: use it to give applicable line end symbols a fill color other than that of the annotation *(changed in v1.16.16).*

**6.1. Annot**
- **cross_out** (*bool*) — *(new in v1.17.2)* add two diagonal lines to the annotation rectangle. ‘Redact’ annotations only. If not desired, *False* must be specified even if the annotation was created with *False*.

- **rotate** (*int*) — new rotation value. Default (-1) means no change. Supports ‘FreeText’ and several other annotation types (see `Annot.set_rotation()`).\(^1\) Only choose 0, 90, 180, or 270 degrees for ‘FreeText’. Otherwise any integer is acceptable.

  **Return type**  bool

**file_info()**  
Basic information of the annot’s attached file.

  **Return type**  dict  
  **Returns**  a dictionary with keys `filename`, `ufilename`, `desc` (description), `size` (uncompressed file size), `length` (compressed length) for FileAttachment annot types, else *None*.

**get_file()**  
Returns attached file content.

  **Return type**  bytes  
  **Returns**  the content of the attached file.

**update_file** (*buffer=None, filename=None, ufilename=None, desc=None*)  
Updates the content of an attached file. All arguments are optional. No arguments lead to a no-op.

  **Parameters**
  - **buffer** (*bytes|bytearray|BytesIO*) — the new file content. Omit to only change meta-information.

    *(Changed in version 1.14.13)* *io.BytesIO* is now also supported.
  - **filename** (*str*) — new filename to associate with the file.
  - **ufilename** (*str*) — new unicode filename to associate with the file.
  - **desc** (*str*) — new description of the file content.

**get_sound()**  
Return the embedded sound of an audio annotation.

  **Return type**  dict  
  **Returns**  the sound audio file and accompanying properties. These are the possible dictionary keys, of which only “rate” and “stream” are always present.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rate</td>
<td>(float, requ.) samples per second</td>
</tr>
<tr>
<td>channels</td>
<td>(int, opt.) number of sound channels</td>
</tr>
<tr>
<td>bps</td>
<td>(int, opt.) bits per sample value per channel</td>
</tr>
<tr>
<td>encoding</td>
<td>(str, opt.) encoding format: Raw, Signed, muLaw, ALaw</td>
</tr>
<tr>
<td>compression</td>
<td>(str, opt.) name of compression filter</td>
</tr>
<tr>
<td>stream</td>
<td>(bytes, requ.) the sound file content</td>
</tr>
</tbody>
</table>

\(^1\) Rotating an annotation generally also changes its rectangle. Depending on how the annotation was defined, the original rectangle in general is not reconstructible by setting the rotation value to zero. This information may be lost.
opacity
The annotation’s transparency. If set, it is a value in range \([0, 1]\). The PDF default is 1. However, in an effort to tell the difference, we return -1.0 if not set.

Return type float

parent
The owning page object of the annotation.

Return type Page

rotation
The annot rotation.

Return type int

Returns a value \([-1, 359]\). If rotation is not at all, -1 is returned (and implies a rotation angle of 0). Other possible values are normalized to some value \(0 \leq \text{angle} < 360\).

rect
The rectangle containing the annotation.

Return type Rect

next
The next annotation on this page or None.

Return type Annot

type
A number and one or two strings describing the annotation type, like \([2, \text{‘FreeText’, ‘FreeTextCallout’}]\). The second string entry is optional and may be empty. See the appendix Annotation Types for a list of possible values and their meanings.

Return type list

info
A dictionary containing various information. All fields are optional strings. If an information is not provided, an empty string is returned.

- name – e.g. for ‘Stamp’ annotations it will contain the stamp text like “Sold” or “Experimental”, for other annot types you will see the name of the annot’s icon here (“PushPin” for FileAttachment).
- content – a string containing the text for type Text and FreeText annotations. Commonly used for filling the text field of annotation pop-up windows.
- title – a string containing the title of the annotation pop-up window. By convention, this is used for the annotation author.
- creationDate – creation timestamp.
- modDate – last modified timestamp.
- subject – subject.
- id – (new in version 1.16.10) a unique identification of the annotation. This is taken from PDF key /NM. Annotations added by PyMuPDF will have a unique name, which appears here.

Return type dict

flags
An integer whose low order bits contain flags for how the annotation should be presented.

Return type int
line_ends
A pair of integers specifying start and end symbol of annotations types ‘FreeText’, ‘Line’, ‘PolyLine’, and ‘Polygon’. None if not applicable. For possible values and descriptions in this list, see the Adobe PDF References, table 8.27 on page 630.

Return type tuple

vertices
A list containing a variable number of point (“vertices”) coordinates (each given by a pair of floats) for various types of annotations:

• ‘Line’ – the starting and ending coordinates (2 float pairs).
• ‘FreeText’ – 2 or 3 float pairs designating the starting, the (optional) knee point, and the ending coordinates.
• ‘PolyLine’ / ‘Polygon’ – the coordinates of the edges connected by line pieces (n float pairs for n points).
• text markup annotations – 4 float pairs specifying the QuadPoints of the marked text span (see Adobe PDF References, page 634).
• ‘Ink’ – list of one to many sublists of vertex coordinates. Each such sublist represents a separate line in the drawing.

Return type list

colors
dictionary of two lists of floats in range $0 \leq float \leq 1$ specifying the “stroke” and the interior (“fill”) colors. The stroke color is used for borders and everything that is actively painted or written (“stroked”). The fill color is used for the interior of objects like line ends, circles and squares. The lengths of these lists implicitly determine the colorspace used: 1 = GRAY, 3 = RGB, 4 = CMYK. So “[1.0, 0.0, 0.0]” stands for RGB color red. Both lists can be empty if no color is specified.

Return type dict

xref
The PDF xref.

Return type int

popup_xref
The PDF xref of the associated Popup annotation. Zero if non-existent.

Return type int

has_popup
Whether the annotation has a Popup annotation.

Return type bool

is_open
Whether the annotation’s Popup is open – or the annotation itself (‘Text’ annotations only).

Return type bool

popup_rect
The rectangle of the associated Popup annotation. Infinite rectangle if non-existent.

Return type Rect
border
A dictionary containing border characteristics. Empty if no border information exists. The following keys may be present:

- `width` – a float indicating the border thickness in points. The value is -1.0 if no width is specified.
- `dashes` – a sequence of integers specifying a line dash pattern. [] means no dashes, [n] means equal on-off lengths of n points, longer lists will be interpreted as specifying alternating on-off length values. See the Adobe PDF References page 217 for more details.
- `style` – 1-byte border style: “S” (Solid) = solid rectangle surrounding the annotation, “D” (Dashed) = dashed rectangle surrounding the annotation, the dash pattern is specified by the `dashes` entry, “B” (Beveled) = a simulated embossed rectangle that appears to be raised above the surface of the page, “I” (Inset) = a simulated engraved rectangle that appears to be recessed below the surface of the page, “U” (Underline) = a single line along the bottom of the annotation rectangle.

Return type dict

6.1.1 Annotation Icons in MuPDF

This is a list of icons referencable by name for annotation types ‘Text’ and ‘FileAttachment’. You can use them via the `icon` parameter when adding an annotation, or use the as argument in `Annot.setName()`. It is left to your discretion which item to choose when – no mechanism will keep you from using e.g. the “Speaker” icon for a ‘FileAttachment’.

- PushPin
- Graph
- Paperclip
- Tag
- Note
- Comment
- Help
- Insert
- Key
- NewParagraph
- Paragraph
- Mic
- Speaker
- Star (default if none of the above)
6.1.2 Example

Change the graphical image of an annotation. Also update the “author” and the text to be shown in the popup window:

```python
doc = fitz.open("circle-in.pdf")
page = doc[0]  # page 0
annot = page.firstAnnot  # get the annotation
annot.set_border(dashes=[3])  # set dashes to "3 on, 3 off ..."

# set stroke and fill color to some blue
annot.set_colors({"stroke":(0, 0, 1), "fill":(0.75, 0.8, 0.95)})
info = annot.info  # get info dict
info["title"] = "Jorj X. McKie"  # set author

# text in popup window ...
info["content"] = "I changed border and colors and enlarged the image by 20%.
info["subject"] = "Demonstration of PyMuPDF"  # some PDF viewers also show this
annot.set_info(info)  # update info dict
r = annot.rect  # take annot rect
r.x1 = r.x0 + r.width * 1.2  # new location has same top-left
r.y1 = r.y0 + r.height * 1.2  # but 20% longer sides
annot.set_rect(r)  # update rectangle
annot.update()  # update the annot's appearance
doc.save("circle-out.pdf")  # save
```

This is how the circle annotation looks like before and after the change (pop-up windows displayed using Nitro PDF viewer):

![](image)

6.2 Colorspace

Represents the color space of a Pixmap.

Class API
class Colorspace

__init__(self, n)

Constructor

Parameters n (int) – A number identifying the colorspace. Possible values are CS_RGB, CS_GRAY and CS_CMYK.

name

The name identifying the colorspace. Example: fitz.csCMYK.name = ‘DeviceCMYK’.

Type str

n

The number of bytes required to define the color of one pixel. Example: fitz.csCMYK.n == 4.

type int

Predefined Colorspaces

For saving some typing effort, there exist predefined colorspace objects for the three available cases.

- csRGB = fitz.Colorspace(fitz.CS_RGB)
- csGRAY = fitz.Colorspace(fitz.CS_GRAY)
- csCMYK = fitz.Colorspace(fitz.CS_CMYK)

6.3 DisplayList

DisplayList is a list containing drawing commands (text, images, etc.). The intent is two-fold:

1. as a caching-mechanism to reduce parsing of a page
2. as a data structure in multi-threading setups, where one thread parses the page and another one renders pages.

This aspect is currently not supported by PyMuPDF.

A display list is populated with objects from a page, usually by executing Page.getDisplayList(). There also exists an independent constructor.

“Replay” the list (once or many times) by invoking one of its methods run(), getPixmap() or get_textpage().

<table>
<thead>
<tr>
<th>Method</th>
<th>Short Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>run()</td>
<td>Run a display list through a device.</td>
</tr>
<tr>
<td>getPixmap()</td>
<td>generate a pixmap</td>
</tr>
<tr>
<td>get_textpage()</td>
<td>generate a text page</td>
</tr>
<tr>
<td>rect</td>
<td>mediabox of the display list</td>
</tr>
</tbody>
</table>

Class API

class DisplayList

__init__(self, mediabox)

Create a new display list.

Parameters mediabox (Rect) – The page’s rectangle.

Return type DisplayList
run \((device, matrix, area)\)
Run the display list through a device. The device will populate the display list with its “commands” (i.e. text extraction or image creation). The display list can later be used to “read” a page many times without having to re-interpret it from the document file.

You will most probably instead use one of the specialized run methods below – `getPixmap()` or `get_textpage()`.

**Parameters**
- **device** (`Device`) – Device
- **matrix** (`Matrix`) – Transformation matrix to apply to the display list contents.
- **area** (`Rect`) – Only the part visible within this area will be considered when the list is run through the device.

**getPixmap** (`matrix=fitz.Identity, colorspace=fitz.csRGB, alpha=0, clip=None`)
Run the display list through a draw device and return a pixmap.

**Parameters**
- **matrix** (`Matrix`) – matrix to use. Default is the identity matrix.
- **colorspace** (`Colorspace`) – the desired colorspace. Default is RGB.
- **alpha** (`int`) – determine whether or not (0, default) to include a transparency channel.
- **clip** (`IRect` or `Rect`) – an area of the full mediabox to which the pixmap should be restricted.

**Return type** `Pixmap`
**Returns** pixmap of the display list.

**get_textpage** (`flags`)  
Run the display list through a text device and return a text page.

**Parameters**  
flags (`int`) – control which information is parsed into a text page. Default value in PyMuPDF is `3 = TEXT_PRESERVE_LIGATURES | TEXT_PRESERVE_WHITESPACE`, i.e. ligatures are **passed through**, white spaces are **passed through** (not translated to spaces), and images are **not included**. See Preserve Text Flags.

**Return type** `TextPage`
**Returns** text page of the display list.

**rect**  
Contains the display list's mediabox. This will equal the page's rectangle if it was created via `Page.getDisplayList()`.
**Type** `Rect`

### 6.4 Document

This class represents a document. It can be constructed from a file or from memory.

There exists the alias `open` for this class, i.e. `fitz.Document(...)` and `fitz.open(...)` do exactly the same thing.

For details on **embedded files** refer to Appendix 3.
Note: Starting with v1.17.0, a new page addressing mechanism for EPUB files only is supported. This document type is internally organized in chapters such that pages can most efficiently be found by their so-called “location”. The location is a tuple \((chapter, pno)\) consisting of the chapter number and the page number in that chapter. Both numbers are zero-based.

While it is still possible to locate a page via its (absolute) number, doing so may mean that the complete EPUB document must be layouted before the page can be addressed. This may have a significant performance impact if the document is very large. Using the page’s \((chapter, pno)\) prevents this from happening.

To maintain a consistent API, PyMuPDF supports the page location syntax for all file types – documents without this feature simply have just one chapter. Document.load_page() and the equivalent index access now also support a location argument.

There are a number of methods for converting between page numbers and locations, for determining the chapter count, the page count per chapter, for computing the next and the previous locations, and the last page location of a document.

Class API

class Document

```python
__init__(self, filename=None, stream=None, filetype=None, rect=None, width=0, height=0, fontsize=11)
```

Creates a Document object.

- With default parameters, a new empty PDF document will be created.
- If stream is given, then the document is created from memory and either filename or filetype must indicate its type.
- If stream is None, then a document is created from the file given by filename. Its type is inferred from the extension, which can be overruled by specifying filetype.

Parameters

- **filename** (str, pathlib) – A UTF-8 string or pathlib object containing a file path (or a file type, see below).
- **stream** (bytes, bytearray, BytesIO) – A memory area containing a supported document. Its type must be specified by either filename or filetype.

(Changed in version 1.14.13) io.BytesIO is now also supported.
- **filetype** (str) – A string specifying the type of document. This may be something looking like a filename (e.g. “x.pdf”), in which case MuPDF uses the extension to determine the type, or a mime type like application/pdf. Just using strings like “pdf” will also work.
- **rect** (rect_like) – a rectangle specifying the desired page size. This parameter is only meaningful for documents with a variable page layout (“reflowable” documents), like e-books or HTML, and ignored otherwise. If specified, it must be a non-empty, finite rectangle with top-left coordinates (0, 0). Together with parameter fontsize, each page will be accordingly laid out and hence also determine the number of pages.
- **width** (float) – may used together with height as an alternative to rect to specify layout information.
- **height** (float) – may used together with width as an alternative to rect to specify layout information.
• \texttt{fontsize (float)} – the default fontsize for reflowable document types. This parameter is ignored if none of the parameters \texttt{rect} or \texttt{width} and \texttt{height} are specified. Will be used to calculate the page layout.

Overview of possible forms (\texttt{open} is a synonym of \texttt{Document}):

```python
>>> # from a file
>>> doc = fitz.open("some.pdf")
>>> doc = fitz.open("some.file", None, "pdf")  # copes with wrong extension
>>> doc = fitz.open("some.file", filetype="pdf")  # copes with wrong extension

>>> # from memory
>>> doc = fitz.open("pdf", mem_area)
>>> doc = fitz.open(None, mem_area, "pdf")
>>> doc = fitz.open(stream=mem_area, filetype="pdf")

>>> # new empty PDF
>>> doc = fitz.open()

```

The Document class can be also be used as a context manager. On exit, the document will automatically be closed.

```python
>>> import fitz
>>> with fitz.open(...) as doc:
...     for page in doc: print("page %i" % page.number)
...     doc.is_closed
... True
>>> 
```

\texttt{get oc (xref)}

(New in v1.18.4)

Return the cross reference number of an \texttt{OCG} or \texttt{OCMD} attached to an image or form xobject.

\textbf{Parameters} \texttt{xref (int)} – the \texttt{xref} of an image or form xobject. Valid such cross reference numbers are returned by \texttt{Document.get_page_images()}, resp. \texttt{Document.get_page_xobjects()}. For invalid numbers, an exception is raised.

\textbf{Return type} \texttt{int}

\textbf{Returns} the cross reference number of an optional contents object or zero if there is none.

\texttt{set oc (xref, ocxref)}

(New in v1.18.4)

If \texttt{xref} represents an image or form xobject, set or remove the cross reference number \texttt{ocxref} of an optional contents object.

\textbf{Parameters}

• \texttt{xref (int)} – the \texttt{xref} of an image or form xobject\textsuperscript{5}. Valid such cross reference numbers are returned by \texttt{Document.get_page_images()}, resp. \texttt{Document.get_page_xobjects()}. For invalid numbers, an exception is raised.

\textsuperscript{5} Examples for “Form XObjects” are created by \texttt{Page.show_pdf_page()}. 

• **ocxref** *(int)* – the **xref** number of an **OCG** / **OCMD**. If not zero, an invalid reference raises an exception. If zero, any OC reference is removed.

layer_configs()  
(New in v1.18.3)

Show optional layer configurations. There always is a standard one, which is not included in the response.

```
>>> for item in doc.layer_configs: print(item)
{'number': 0, 'name': 'my-config', 'creator': ''}
>>> # use 'number' as config identifier in add_ocg
```

**add_layer_config**(name, creator=None, on=None)  
(New in v1.18.3)

Add an optional content configuration. Layers serve as a collection of ON / OFF states for optional content groups. They allow fast visibility switches between different views on the same document.

Parameters

• **name**(str) – arbitrary name.

• **creator**(str) – creating software.

• **on**(sequ) – a sequence of OCG xref numbers which should be set to ON (visible). All other OCGs will be set to OFF.

**switch_layer**(number, as_default=False)  
(New in v1.18.3)

Switch to a document view as defined by the optional layer’s configuration number. This is temporary, except if established as default.

Parameters

• **number**(int) – config number as returned by **Document.layer_configs()**.

• **as_default**(bool) – make this the default configuration.

Activates the ON / OFF states of OCGs as defined in the identified layer. If **as_default=True**, then additionally all layers, including the standard one, are merged and the result is written back to the standard layer, and all optional layers are deleted.

**add_ocg**(name, config=-1, on=True, intent="View", usage="Artwork")  
(New in v1.18.3)

Add an optional content group. An OCG is the most important unit of information to determine object visibility. For a PDF, in order to be regarded as having optional content, at least one OCG must exist.

Parameters

• **name**(str) – arbitrary name. Will show up in supporting PDF viewers.

• **config**(int) – layer configuration number. Default -1 is the standard configuration.

• **on**(bool) – standard visibility status for objects pointing to this OCG.

• **intent**(str, list) – a string or list of strings declaring the visibility intents. There are two PDF standard values to choose from: “View” and “Design”. Default is “View”. Correct spelling is important.

• **usage**(str) – another influencer for OCG visibility. This will become part of the OCG’s /Usage key. There are two PDF standard values to choose from: “Artwork” and “Technical”. Default is “Artwork”. Please only change when required.
Returns \texttt{xref} of the created OCG. Use as entry for \texttt{oc} parameter in supporting objects.

\textbf{Note:} Multiple OCGs with identical parameters may be created. This will not cause problems. Garbage option 3 of \texttt{Document.save()} will get rid of any duplicates.

\begin{verbatim}
set_ocmd(xref=0, ocgs=None, policy="AnyOn", ve=None)
\end{verbatim}

Create or update an OCMD (optional content membership dictionary).

**Parameters**

- \texttt{xref (int)} – \texttt{xref} of the OCMD to be updated, or 0 for a new OCMD.
- \texttt{ocgs (list)} – a sequence of \texttt{xref} numbers of existing OCG PDF objects.
- \texttt{policy (str)} – one of “AnyOn” (default), “AnyOff”, “AllOn”, “AllOff” (mixed or lower case).
- \texttt{ve (list)} – a “visibility expression”. This is a list of arbitrarily nested other lists – see explanation below. Use as an alternative to the combination \texttt{ocgs / policy} if you need to formulate more complex conditions.

**Return type** int

Returns \texttt{xref} of the OCMD. Use as \texttt{oc=xref} parameter in supporting objects, and respectively in \texttt{Document.set_oc()} or \texttt{Annot.set_oc()}.

\textbf{Note:} The purpose of OCMDS is to more flexibly determine visibility. An OCMD actually is a boolean expression: it evaluates the current visibility of one or more optional content groups and then computes its own ON (true) or OFF (false) state.

There are two ways to formulate the OCMD’s visibility:

1. Use the combination of \texttt{ocgs} and \texttt{policy}: The \texttt{policy} value is interpreted as follows:

   - AnyOn – (default) true if at least one OCG is ON.
   - AnyOff – true if at least one OCG is OFF.
   - AllOn – true if all OCGs are ON.
   - AllOff – true if all OCGs are OFF.

   Suppose you want two PDF objects be displayed exactly one at a time (if one is ON, then the other one must be OFF):

   Solution: use an OCG for object 1 and an OCMD for object 2. Create the OCMD via \texttt{set_ocmd(ocgs=[xref], policy="AllOff")}, with the \texttt{xref} of the OCG.

2. Use the \texttt{visibility expression} \texttt{ve}: This is a list of a logical expression keyword (string) followed by integers or other lists. The possible logical expressions are “\texttt{and}”, “\texttt{or}”, and “\texttt{not}”. The integers must be \texttt{xref} numbers of OCGs. The syntax of this parameter is a bit awkward, but quite powerful:

   - Each list, including the top one, must start with a logical expression.
   - If the first item is a “\texttt{not}”, then the list must have exactly two items. If it is “\texttt{and}” or “\texttt{or}”, any number of other items may follow.
• Items following the logical expression may be either integers or other lists. An integer must be the xref of an OCG. A list must conform to the rules above.

Examples:
• set_ocmd(ve=["or", 4, ["not", 5], ["and", 6, 7]]). This delivers ON if the following is true: “4 is ON, or 5 is OFF, or 6 and 7 are both ON”.
• set_ocmd(ve=["not", xref]). This has the same effect as the OCMD example created under 1.

For more details and examples see page 367 of Adobe PDF References. Also do have a look at example scripts here.

Visibility expressions, /VE, are part of the PDF version 1.6 specification. If you are using an older PDF consumer software, you hence may find it unsupported (i.e. ignored).

---

**get_ocmd** (<code>xref</code>)
(New in v1.18.4)

Retrieve the definition of an OCMD (optional content membership dictionary).

**Parameters**
<code>xref (int)</code> – the xref of the OCMD.

**Return type**
dict

**Returns**
a dictionary with the keys <code>xref</code>, <code>ocgs</code>, <code>policy</code> and <code>ve</code>.

**get_oc_states** (config=-1)
(New in v1.18.3)

List of optional content groups by status in the specified configuration. This is a dictionary with lists of cross reference numbers for OCGs that occur in the arrays /ON, /OFF or in some radio button group (/RBGroups).

**Parameters**
<code>config (int)</code> – the configuration layer (default is the standard config layer).

```python
>>> pprint(doc.get_oc_states())
{'off': [8, 9, 10], 'on': [5, 6, 7], 'rbgroups': [[7, 10]]}
```

**set_oc_states** (config, on=None, off=None, basestate=None, rbgroups=None)
(New in v1.18.3)

Mass status changes of optional content groups. **Permanently** sets the status of OCGs.

**Parameters**

• <code>config (int)</code> – desired configuration layer, choose -1 for the default one.

• <code>on (list)</code> – list of xref of OCGs to set ON. Replaces previous values. An empty list will cause no OCG being set to ON anymore. Should be specified if basestate="ON" is used.

• <code>off (list)</code> – list of xref of OCGs to set OFF. Replaces previous values. An empty list will cause no OCG being set to OFF anymore. Should be specified if basestate="OFF" is used.

• <code>basestate (str)</code> – desired state of OCGs that are not mentioned in on resp. off. Possible values are “ON”, “OFF” or “Unchanged”. Upper / lower case possible.
• **rbgroups** *(list)* – a list of lists. Replaces previous values. Each sublist should contain two or more OCG xrefs. OCGs in the same sublist are handled like buttons in a radio button group: setting one to ON automatically sets all other group members to OFF.

Values *None* will not change the corresponding PDF array.

```python
>>> doc.set_oc_states(-1, basestate="OFF")  # only changes the base state
>>> pprint(doc.get_oc_states())
{'basestate': 'OFF', 'off': [8, 9, 10], 'on': [5, 6, 7], 'rbgroups': [[7, 10]]}
```

**get_ocgs**
*(New in v1.18.3)*

Details of all optional content groups. This is a dictionary of dictionaries like this (key is the OCG’s xref):

```python
>>> pprint(doc.get_ocgs())
{13: {'on': True, 'intent': ['View', 'Design'], 'name': 'Circle', 'usage': 'Artwork'}, 14: {'on': True, 'intent': ['View', 'Design'], 'name': 'Square', 'usage': 'Artwork'}, 15: {'on': False, 'intent': ['View'], 'name': 'Square', 'usage': 'Artwork'}}
```

**layer_ui_configs**
*(New in v1.18.3)*

Show the visibility status of optional content that is modifyable by the user interface of supporting PDF viewers. Example:

```python
>>> pprint(doc.layer_ui_configs())
({'depth': 0, 'locked': False, 'number': 0, 'on': True, 'text': 'Circle', 'type': 'checkbox'}, {'depth': 0, 'locked': False, 'number': 1, 'on': False, 'text': 'Square', 'type': 'checkbox'})
```

# Note:

- Only reports items contained in the currently selected layer configuration.
- The meaning of the dictionary keys is as follows:
  - *depth*: item’s nesting level in the */Order* array
  - *locked*: whether changing the item’s state is prohibited
- **number**: running sequence number
- **on**: item state
- **text**: text string or name field of the originating OCG
- **type**: one of “label” (set by a text string), “checkbox” (set by a single OCG) or “radiobox” (set by a set of connected OCGs)

**set_layer_ui_config** *(number, action=0)*
*(New in v1.18.3)*

Modify OC visibility status of content groups. This is analogous to what supporting PDF viewers would offer.

**Note**: Visibility is not a property stored with the OCG. It is not even an information necessarily present in the PDF document at all. Instead, the current visibility is **temporarily** set using the user interface of some supporting PDF consumer software. The same type of functionality is offered by this method.

To make permanent changes, use `Document.set_oc_states()`.

**Parameters**

- **number** *(in)* – number as returned by `Document.layer_ui_configs()`.
- **action** *(int)* – 0 = set on (default), 1 = toggle on/off, 2 = set off.

**Example**:

```python
>>> # let's make above "Square" visible:
>>> doc.set_layer_ui_config(1, action=0)
>>> pprint(doc.layer_ui_configs())
({'depth': 0,
  'locked': False,
  'number': 0,
  'on': True,
  'text': 'Circle',
  'type': 'checkbox'},
 {'depth': 0,
  'locked': False,
  'number': 1,
  'on': True, # <===
  'text': 'Square',
  'type': 'checkbox'})
>>>```

**authenticate** *(password)*

Decrypts the document with the string `password`. If successful, document data can be accessed. For PDF documents, the “owner” and the “user” have different privileges, and hence different passwords may exist for these authorization levels. The method will automatically establish the appropriate access rights for the provided password.

**Parameters**

- **password** *(str)* – owner or user password.

**Return type** *int*

**Returns**

- a positive value if successful, zero otherwise. If positive, the indicator `Document.is_encrypted` is set to `False`. Positive return codes carry the following information detail:
• bit 0 set => authenticated, but no password required – happens if method was used although needsPass() was zero.

• bit 1 set => authenticated with the user password.

• bit 2 set => authenticated with the owner password.

**get_page_numbers** *(label, only_one=False)*

*(New in v 1.18.6)*

PDF only: Return a list of page numbers that have the specified label – note that labels may not be unique in a PDF. This implies a sequential search through all page numbers to compare their labels.

**Parameters**

- **label** *(str)* – the label to look for, e.g. “vii” (Roman number 7).

- **only_one** *(bool)* – stop after first hit. Useful e.g. if labelling is known to be unique, there are many pages, etc. The default will check every page number.

**Return type** list

**Returns** list of page numbers that have this label. Empty if none found, no labels defined, etc.

**get_page_labels** *

*(New in v1.18.7)*

PDF only: Extract the list of page label definitions. Typically used for modifications before feeding it into Document.set_page_labels().

**Returns** a list of dictionaries as defined in Document.set_page_labels().

**set_page_labels** *(labels)*

*(New in v1.18.6)*

PDF only: Add or update the page label definitions of the PDF.

**Parameters** labels *(list)* – a list of dictionaries. Each dictionary defines a label building rule and a 0-based “start” page number. That start page number is the first for which the label definition is valid. Each dictionary has up to 4 items and looks like {'startpage': int, 'prefix': str, 'style': str, 'firstpagenum': int} and has the following items.

- **startpage**: (int) the first page number (0-based) to apply the label rule. This key **must be present**. The rule is applied to all subsequent pages until either end of document or superseded by the rule with the next larger page number.

- **prefix**: (str) an arbitrary string to start the label with, e.g. “A-“. Default is “”.

- **style**: (str) the numbering style. Available are “D” (decimal), “r”/”R” (Roman numbers, lower or upper case), and “a”/”A” (lower or upper case alphabetical numbering: “a” through “z”, then “aa” through “az”, etc.). Default is “”. If “”, no numbering will take place and the pages in that range will receive the same label consisting of the prefix value. If prefix is also omitted, then the label will be “”.

- **firstpagenum**: (int) start numbering with this value. Default is 1, smaller values are ignored.

For example:
will generate the labels “A-10”, “A-11”, “A-12”, “A-13”, “1”, “2”, “3”, … for pages 6, 7 and so on until end of document. Pages 0 through 5 will have the label “”.

**make_bookmark** *(loc)*  
*(New in v.1.17.3)* Return a page pointer in a reflowable document. After re-layouting the document, the result of this method can be used to find the new location of the page.

**Note:** Do not confuse with items of a table of contents, TOC.

**Parameters**  
loc *(list, tuple)* – page location. Must be a valid *(chapter, pno)*.

**Return type**  
pointer

**Returns** a long integer in pointer format. To be used for finding the new location of the page after re-layouting the document. Do not touch or re-assign.

**find_bookmark** *(bookmark)*  
*(New in v.1.17.3)* Return the new page location after re-layouting the document.

**Parameters**  
bookmark *(pointer)* – created by Document.make_bookmark().

**Return type**  
tuple

**Returns** the new (chapter, pno) of the page.

**chapter_page_count** *(chapter)*  
*(New in v.1.17.0)* Return the number of pages of a chapter.

**Parameters**  
chapter *(int)* – the 0-based chapter number.

**Return type**  
int

**Returns** number of pages in chapter. Relevant only for document types with chapter support (EPUB currently).

**next_location** *(page_id)*  
*(New in v.1.17.0)* Return the location of the following page.

**Parameters**  
page_id *(tuple)* – the current page id. This must be a tuple *(chapter, pno)* identifying an existing page.

**Returns** The tuple of the following page, i.e. either *(chapter, pno + 1)* or *(chapter + 1, 0)*, or the empty tuple () if the argument was the last page. Relevant only for document types with chapter support (EPUB currently).

**prev_location** *(page_id)*  
*(New in v.1.17.0)* Return the locator of the preceding page.

**Parameters**  
page_id *(tuple)* – the current page id. This must be a tuple *(chapter, pno)* identifying an existing page.

**Returns** The tuple of the preceding page, i.e. either *(chapter, pno - 1)* or the last page of the receding chapter, or the empty tuple () if the argument was the first page. Relevant only for document types with chapter support (EPUB currently).

**load_page** *(page_id=0)*  
Create a Page object for further processing (like rendering, text searching, etc.).
For document types supporting a so-called “chapter structure” (like EPUB), pages can also be loaded via the combination of chapter number and relative page number, instead of the absolute page number. This should **significantly speed up access** for large documents.

**Parameters**

- `page_id (int, tuple)` *(Changed in v1.17.0)*

  Either a 0-based page number, or a tuple `(chapter, pno)`. For an integer, any `-inf < page_id < page_count` is acceptable. While `page_id` is negative, `page_count` will be added to it. For example: to load the last page, you can use `doc.load_page(-1)`. After this you have `page.number = doc.page_count - 1`.

  For a tuple, `chapter` must be in range `Document.chapter_count`, and `pno` must be in range `Document.chapter_page_count()` of that chapter. Both values are 0-based.

  Using this notation, `Page.number` will equal the given tuple. Relevant only for document types with chapter support (EPUB currently).

**Return type** `Page`

**Note:** Documents also follow the Python sequence protocol with page numbers as indices: `doc.load_page(n) == doc[n]`.

For **absolute page numbers** only, expressions like “for page in doc: ...” and “for page in reversed(doc): ...” will successively yield the document’s pages. Refer to `Document.pages()` which allows processing pages as with slicing.

You can also use index notation with the new chapter-based page identification: use `page = doc[(5, 2)]` to load the third page of the sixth chapter.

To maintain a consistent API, for document types not supporting a chapter structure (like PDFs), `Document.chapter_count` is 1, and pages can also be loaded via tuples `(0, pno)`. See this\(^3\) footnote for comments on performance improvements.

**reload_page(page)** *(New in version 1.16.10)*

PDF only: Provide a new copy of a page after finishing and updating all pending changes.

**Parameters**

- `page (Page)` – page object.

**Return type** `Page`

**Returns** a new copy of the same page. All pending updates (e.g. to annotations or widgets) will be finalized and a fresh copy of the page will be loaded. .. note:: In a typical use case, a page `Pixmap` should be taken after annotations / widgets have been added or changed. To force all those changes being reflected in the page structure, this method re-instates a fresh copy while keeping the object hierarchy “document -> page -> annotation(s)” intact.

**page_cropbox(pno)** *(New in version 1.17.7)*

PDF only: Return the unrotated page rectangle – **without reading the page** (via `Document.load_page()`). This is meant for internal purpose requiring best possible performance.

**Parameters**

- `pno (int)` – 0-based page number.

**Returns** `Rect` of the page like `Page.rect()`, but ignoring any rotation.

---

\(^3\) For applicable (EPUB) document types, loading a page via its absolute number may result in layouting a large part of the document, before the page can be accessed. To avoid this performance impact, prefer chapter-based access. Use convenience methods / attributes `Document.next_location()`, `Document.prev_location()` and `Document.last_location` for maintaining a high level of coding efficiency.
**page_xref** *(pno)*

*New in version 1.17.7*

PDF only: Return the **xref** of the page **without reading the page** (via *Document.load_page()*). This is meant for internal purposes requiring best possible performance.

**Parameters**

- **pno** *(int)* – 0-based page number.

**Returns**

**xref** of the page like *Page.xref*.

**pages** *(start=None, stop=None, step=None)*

*New in version 1.16.4*

A generator for a given range of pages. Parameters have the same meaning as in the built-in function *range()*). Intended for expressions of the form “for page in doc.pages(start, stop, step): …”.

**Parameters**

- **start** *(int)* – start iteration with this page number. Default is zero, allowed values are `-inf < start < page_count`. While this is negative, *page_count* is added **before** starting the iteration.

- **stop** *(int)* – stop iteration at this page number. Default is *page_count*, possible are `-inf < stop <= page_count`. Larger values are **silently replaced** by the default. Negative values will cyclically emit the pages in reversed order. As with the built-in *range()*), this is the first page **not** returned.

- **step** *(int)* – stepping value. Defaults are 1 if start < stop and -1 if start > stop. Zero is not allowed.

**Returns**

a generator iterator over the document’s pages. Some examples:

- ”doc.pages()” emits all pages.
- ”doc.pages(4, 9, 2)” emits pages 4, 6, 8.
- ”doc.pages(0, None, 2)” emits all pages with even numbers.
- ”doc.pages(-2)” emits the last two pages.
- ”doc.pages(-1, -1)” emits all pages in reversed order.
- ”doc.pages(-1, -10)” emits pages in reversed order, starting with the last page **repeatedly**.

For a 4-page document the following page numbers are emitted: 3, 2, 1, 0, 3, 2, 1, 0, 3.

**convert_to_pdf** *(from_page=-1, to_page=-1, rotate=0)*

Create a PDF version of the current document and write it to memory. **All document types** are supported. The parameters have the same meaning as in *insert_pdf()*). In essence, you can restrict the conversion to a page subset, specify page rotation, and revert page sequence.

**Parameters**

- **from_page** *(int)* – first page to copy (0-based). Default is first page.

- **to_page** *(int)* – last page to copy (0-based). Default is last page.

- **rotate** *(int)* – rotation angle. Default is 0 (no rotation). Should be $n \times 90$ with an integer n (not checked).

**Return type** bytes
Returns

a Python bytes object containing a PDF file image. It is created by internally using tobytes(garbage=4, deflate=True). See tobytes(). You can output it directly to disk or open it as a PDF. Here are some examples:

```python
>>> # convert an XPS file to PDF
>>> xps = fitz.open("some.xps")
>>> pdfbytes = xps.convert_to_pdf()

>>> # either do this --->
>>> pdf = fitz.open("pdf", pdfbytes)
>>> pdf.save("some.pdf")

>>> # or this --->
>>> pdfout = open("some.pdf", "wb")
>>> pdfout.tobytes(pdfbytes)
>>> pdfout.close()
```

```python
>>> # copy image files to PDF pages
>>> # each page will have image dimensions
>>> doc = fitz.open()  # new PDF
>>> imglist = [... image file names ...]  # e.g. a directory listing
>>> for img in imglist:
    imgdoc=fitz.open(img)  # open image as a document
    pdfbytes=imgdoc.convert_to_pdf()  # make a 1-page PDF of it
    imgpdf=fitz.open("pdf", pdfbytes)
    doc.insert_pdf(imgpdf)  # insert the image PDF

>>> doc.save("allmyimages.pdf")
```

Note: The method uses the same logic as the mutool convert CLI. This works very well in most cases – however, beware of the following limitations.

- Image files: perfect, no issues detected. Apparently however, image transparency is ignored. If you need that (like for a watermark), use Page.insertImage() instead. Otherwise, this method is recommended for its much better performance.

- XPS: appearance very good. Links work fine, outlines (bookmarks) are lost, but can easily be recovered\(^2\).

- EPUB, CBZ, FB2: similar to XPS.

- SVG: medium. Roughly comparable to svglib.

get_toc\((\text{simple=}True)\)

Creates a table of contents (TOC) out of the document’s outline chain.

Parameters simple\(\text{bool}\) – Indicates whether a simple or a detailed TOC is required. If False, each item of the list also contains a dictionary with linkDest details for each outline entry.

Return type list

Returns

a list of lists. Each entry has the form \([lvl, title, page, dest]\). Its entries have the following meanings:

\(^2\) However, you can use Document.get_toc() and Page.getLinks() (which are available for all document types) and copy this information over to the output PDF. See demo pdf-converter.py.
- *lvl* – hierarchy level (positive *int*). The first entry is always 1. Entries in a row are either *equal*, *increase* by 1, or *decrease* by any number.
- *title* – title (*str*)
- *page* – 1-based page number (*int*). If -1 either no destination or outside document.
- *dest* – (*dict*) included only if *simple=False*. Contains details of the TOC item as follows:
  - *kind*: destination kind, see *Link Destination Kinds*.
  - *file*: filename if kind is *LINK_GOTOR* or *LINK_LAUNCH*.
  - *page*: target page, 0-based, *LINK_GOTOR* or *LINK_GOTO* only.
  - *to*: position on target page (*Point*).
  - *zoom*: (float) zoom factor on target page.
  - *xref*: *xref* of the item (0 if no PDF).
  - *color*: item color in PDF RGB format (**red**, **green**, **blue**), or omitted (always omitted if no PDF).
  - *bold*: true if bold item text or omitted. PDF only.
  - *italic*: true if italic item text, or omitted. PDF only.
  - *collapse*: true if sub-items are folded, or omitted. PDF only.

**xref_get_keys** (*xref*)

(NEW in v 1.18.7)

PDF only: Return the PDF dictionary keys of the object provided by its xref number.

**Parameters**

- *xref* (*int*) – the *xref*.

**Returns**

a tuple of dictionary keys present in object *xref*. Example:

```python
>>> from pprint import pprint
>>> import fitz
>>> doc=fitz.open("pymupdf.pdf")
>>> xref = doc.page_xref(0)  # xref of page 0
>>> pprint(doc.xref_get_keys(xref))
('Type', 'Contents', 'Resources', 'MediaBox', 'Parent')
```

**xref_get_key** (*xref, key*)

(NEW in v 1.18.7)

PDF only: Return type and value of a PDF dictionary key of an xref.

**Parameters**

- *xref* (*int*) – the *xref*.
- *key* (*str*) – the desired PDF key. Must **exactly** match (case-sensitive) one of the keys contained in *Document.xref_get_keys()*.

**Returns**

a tuple (type, value), where type is one of “*xref*”, “array”, “dict”, “int”, “float” “null”, “bool”, “float”, “name”, “string” or “unknown” (should not occur). Independent of “type”, the value of the key is **always** formatted as a string – see the following example – and a faithful
reflection of what is stored in the PDF. An argument like the return value can be used to modify the value of a key of `xref`.

```python
>>> for key in doc.xref_get_keys(xref):
    print(key, "=", doc.xref_get_key(xref, key))
Type = ['name', '/Page']
Contents = ['xref', '1297 0 R']
Resources = ['xref', '1296 0 R']
MediaBox = ['array', '[0 0 612 792]']
Parent = ['xref', '1301 0 R']
>>> xref_set_key(xref, key, value)
```

`xref_set_key(xref, key, value)`  
(New in v 1.18.7)

PDF only: Set the value of a PDF key in the object given by an xref. This is an expert function: if you do not know what you are doing, there is a high risk to render (parts of) the PDF unusable. Please do consult Adobe PDF References about object specification formats (page 51) and the structure of special dictionary types like page objects.

Parameters

- **xref (int)** – the xref.
- **key (str)** – the desired PDF key (without leading “/”). Must not be empty. Any valid PDF key – whether already present in the object (which will be overwritten) – or new. It is possible to use PDF path notation like "Resources/ExtGState" – which sets the value for key "/ExtGState" as a sub-object of "/Resources".
- **value (str)** – the value for the key. It must be a non-empty string and, depending on the desired PDF object type, the following rules must be observed – there is some syntax, but no type checking and no checking of the PDF semantics. Upper or lower case are important!
  - **xref** – must be provided as "nnn 0 R" with a valid xref number nnn of the PDF. The suffix "0 R" is required to be recognizable as a xref.
  - **array** – a string like "[a b c d e f ...]". The brackets are required. Array items must be separated by at least one space (not commas like in Python). An empty array "[]" is possible and equivalent to removing the key. Array items may be any PDF objects, like dictionaries, xrefs, other arrays, etc. Like in Python, array items need not be of the same type.
  - **dict** – a string like "<< ... >>". The brackets are required and must enclose a valid PDF dictionary definition. The empty dictionary "<<>>" is possible and equivalent to removing the key.
  - **int** – an integer formatted as a string.
  - **float** – a float formatted as a string. Scientific notation (with exponents) is not allowed by PDF.
  - **null** – the string "null". This is the PDF equivalent to Python’s None and causes the key to be ignored – however not necessarily removed.
  - **bool** – one of the strings "true" or "false".
  - **name** – a valid PDF name with a leading slash: "/PageLayout".
  - **string** – a valid PDF string. Denote the empty string as "()". Depending on its content, it must be enclosed in bracket types “(…)” or “<<…>>”, and reserved PDF characters must be escaped. If in doubt, we strongly recommend to use...
getPDFstr()! This function automatically determines the required format. E.g. it will do conversions like

```plaintext
fitz.getPDFstr("Pay in $ or €.") = "<feff00500061007900200069006e002000240020006f0072002020ac002e>",
```
or

```plaintext
fitz.getPDFstr("Prices in USD (EUR accepted).") = "(Prices in USD \(EUR accepted\))."
```

**get_page_pixmap(pno, *args, **kwargs)**

Creates a pixmap from page `pno` (zero-based). Invokes `Page.get_page_pixmap()`.

**Parameters**

- `pno (int)` – page number, 0-based in -inf < pno < page_count.

**Return type**

`Pixmap`

**get_page_xobjects(pno)**

PDF only: *(New in v1.16.13)* Return a list of all XObjects referenced by a page.

**Parameters**

- `pno (int)` – page number, 0-based, -inf < pno < page_count.

**Return type**

`list`

**Returns**

A list of (non-image) XObjects. These objects typically represent pages embedded (not copied) from other PDFs. For example, `Page.show_pdf_page()` will create this type of object. An item of this list has the following layout: `(xref, name, invoker, bbox)`, where:

- `xref (int)` is the XObject’s `xref`
- `name (str)` is the symbolic name to reference the XObject
- `invoker (int)` the `xref` of the invoking XObject or zero if the page directly invokes it
- `bbox (tuple)` the boundary box of the XObject’s location on the page in **untransformed coordinates**. To get actual, non-rotated page coordinates, multiply with the page’s transformation matrix `Page.transformationMatrix`.

**get_page_images(pno, full=False)**

PDF only: Return a list of all images (directly or indirectly) referenced by the page.

**Parameters**

- `pno (int)` – page number, 0-based, -inf < pno < page_count.
- `full (bool)` – whether to also include the referencer’s `xref` (which is zero if this is the page).

**Return type**

`list`

**Returns** a list of images shown on this page. Each item looks like

```plaintext
(xref, smask, width, height, bpc, colorspace, alt. colorspace, name, filter, referencer)
```

Where:

- `xref (int)` is the image object number
- `smask (int)` is the object number of its soft-mask image
- `width` and `height (ints)` are the image dimensions
- `bpc (int)` denotes the number of bits per component (normally 8)
- `colorspace (str)` a string naming the colorspace (like `DeviceRGB`)
- `alt. colorspace (str)` is any alternate colorspace depending on the value of `colorspace`
- `name (str)` is the symbolic name by which the image is referenced
filter (str) is the decode filter of the image (Adobe PDF References, pp. 65).

refterencer (int) the xref of the referencer. Zero if directly referenced by the page. Only present if full=True.

See below how this information can be used to extract PDF images as separate files. Another demonstration:

```python
>>> doc = fitz.open("pymupdf.pdf")
>>> doc.get_page_images(0, full=True)
[316, 0, 261, 115, 8, 'DeviceRGB', '', 'Im1', 'DCTDecode', 0]
>>> pix = fitz.Pixmap(doc, 316)  # 316 is the xref of the image
>>> pix
fitz.Pixmap(DeviceRGB, fitz.IRect(0, 0, 261, 115), 0)
```

get_page_fonts (pno, full=False)
PDF only: Return a list of all fonts (directly or indirectly) referenced by the page.

Parameters
- pno (int) – page number, 0-based, -inf < pno < page_count.
- full (bool) – whether to also include the referencer’s xref. If True, the returned items are one entry longer. Use this option if you need to know, whether the page directly references the font. In this case the last entry is 0. If the font is referenced by an /XObject of the page, you will find its xref here.

Return type list

Returns a list of fonts referenced by this page. Each entry looks like
(xref, ext, type, basefont, name, encoding, referencer),
where
- xref (int) is the font object number (may be zero if the PDF uses one of the built-in fonts directly)
- ext (str) font file extension (e.g. “ttf”, see Font File Extensions)
- type (str) is the font type (like “Type1” or “TrueType” etc.)
- basefont (str) is the base font name,
- name (str) is the symbolic name, by which the font is referenced
- encoding (str) the font’s character encoding if different from its built-in encoding (Adobe PDF References, p. 414):
- referencer (int optional) the xref of the referencer. Zero if directly referenced by the page, otherwise the xref of an XObject. Only present if full=True.

Example:

```python
>>> pprint(doc.get_page_fonts(0, full=False))
[(12, 'ttf', 'TrueType', 'FNUUTH+Calibri-Bold', 'R8', ''),
 (13, 'ttf', 'TrueType', 'DOKBTG+Calibri', 'R10', ''),
 (14, 'ttf', 'TrueType', 'NOHSJV+Calibri-Light', 'R12', ''),
 (15, 'ttf', 'TrueType', 'NZNDCL+CourierNewPSMT', 'R14', ''),
 (16, 'ttf', 'Type0', 'MNCSJY+SymbolMT', 'R17', 'Identity-H'),
 (17, 'cff', 'Type1', 'UAEUUY+Helvetica', 'R20', 'WinAnsiEncoding'),
 (18, 'ttf', 'Type0', 'ECPLRU+Calibri', 'R23', 'Identity-H'),
 (19, 'ttf', 'Type0', 'TONAYT+CourierNewPSMT', 'R27', 'Identity-H')]
```
**get_page_text** *(pno, output="text")*

Extracts the text of a page given its page number *pno* (zero-based). Invokes `Page.get_text()`.

**Parameters**

- **pno** *(int)* — page number, 0-based, any value $-\infty < \text{pno} < \text{page_count}$.
- **output** *(str)* — A string specifying the requested output format: text, html, json or xml. Default is text.

**Return type** *str*

**layout** *(rect=None, width=0, height=0, fontsize=11)*

Re-paginate ("reflow") the document based on the given page dimension and fontsize. This only affects some document types like e-books and HTML. Ignored if not supported. Supported documents have True in property `isReflowable`.

**Parameters**

- **rect** *(rect_like)* — desired page size. Must be finite, not empty and start at point (0, 0).
- **width** *(float)* — use it together with `height` as alternative to `rect`.
- **height** *(float)* — use it together with `width` as alternative to `rect`.
- **fontsize** *(float)* — the desired default fontsize.

**select** *(s)*

PDF only: Keeps only those pages of the document whose numbers occur in the list. Empty sequences or elements outside `range(len(doc))` will cause a `ValueError`. For more details see remarks at the bottom or this chapter.

**Parameters**  
**s** *(sequence)* — The sequence (see Using Python Sequences as Arguments in PyMuPDF) of page numbers (zero-based) to be included. Pages not in the sequence will be deleted (from memory) and become unavailable until the document is reopened. **Page numbers can occur multiple times and in any order**: the resulting document will reflect the sequence exactly as specified.

**Note:**

- Page numbers in the sequence need not be unique nor be in any particular order. This makes the method a versatile utility to e.g. select only the even or the odd pages or meeting some other criteria and so forth.
- On a technical level, the method will always create a new pagetree.
- When dealing with only a few pages, methods `copyPage()`, `move_page()`, `delete_page()` are easier to use. In fact, they are also much faster — by at least one order of magnitude when the document has many pages.

**set_metadata** *(m)*

PDF only: Sets or updates the metadata of the document as specified in *m*, a Python dictionary.

**Parameters**  
**m** *(dict)* — A dictionary with the same keys as `metadata` (see below). All keys are optional. A PDF’s format and encryption method cannot be set or changed and will be ignored. If any value should not contain data, do not specify its key or set the value to `None`. 

---

**6.4. Document**

---

119
If you use `{}` all metadata information will be cleared to the string “none”. If you want to selectively change only some values, modify a copy of `doc.metadata` and use it as the argument. Arbitrary unicode values are possible if specified as UTF-8-encoded.

(Changed in v1.18.4) Empty values or “none” are no longer written, but completely omitted.

`get_xml_metadata()`  
PDF only: Get the document XML metadata.

**Return type**  
str

**Returns**  
XML metadata of the document. Empty string if not present or not a PDF.

`set_xml_metadata(xml)`  
PDF only: Sets or updates XML metadata of the document.

**Parameters**  
xml (str) – the new XML metadata. Should be XML syntax, however no checking is done by this method and any string is accepted.

`set_toc(toc, collapse=1)`  
PDF only: Replaces the complete current outline tree (table of contents) with the one provided as the argument. After successful execution, the new outline tree can be accessed as usual via `Document.get_toc()` or via `Document.outline`. Like with other output-oriented methods, changes become permanent only via `save()` (incremental save supported). Internally, this method consists of the following two steps. For a demonstration see example below.

- Step 1 deletes all existing bookmarks.
- Step 2 creates a new TOC from the entries contained in `toc`.

**Parameters**

- toc (sequence) – A list / tuple with all bookmark entries that should form the new table of contents. Output variants of `get_toc()` are acceptable. To completely remove the table of contents specify an empty sequence or None. Each item must be a list with the following format.
  - [lvl, title, page [, dest]] where
    - * lvl is the hierarchy level (int > 0) of the item, which must be 1 for the first item and at most 1 larger than the previous one.
    - * title (str) is the title to be displayed. It is assumed to be UTF-8-encoded (relevant for multibyte code points only).
    - * page (int) is the target page number (attention: 1-based). Must be in valid range if positive. Set it to -1 if there is no target, or the target is external.
    - * dest (optional) is a dictionary or a number. If a number, it will be interpreted as the desired height (in points) this entry should point to on the page. Use a dictionary (like the one given as output by `get_toc(False)`) for a detailed control of the bookmark’s properties, see `Document.get_toc()` for a description.
  - * collapse (int) – (new in version 1.16.9) controls the hierarchy level beyond which outline entries should initially show up collapsed. The default 1 will hence only display level 1, higher levels must be unfolded using the PDF viewer. To unfold everything, specify either a large integer, 0 or None.

**Return type**  
int

**Returns**  
the number of inserted, resp. deleted items.
outline_xref(idx)
(New in v1.17.7)
PDF only: Return the xref of the outline item. This is mainly used for internal purposes.
arg int idx: index of the item in list Document.get_toc().

Returns xref.
del_toc_item(idx)
(New in v1.17.7)
PDF only: Remove this TOC item. This is a high-speed method primarily meant for disabling items, which are pointing to deleted pages. Physically, the item still exists in the TOC tree, but will show an empty title and no longer point to a destination. So the overall TOC structure remains intact.
This also implies that you can reassign the item to a destination when required.

Parameters idx (int) – the index of the item in list Document.get_toc().

set_toc_item(idx, dest_dict=None, kind=None, pno=None, uri=None, title=None, to=None, filename=None, zoom=0)
(Changed in v1.18.6)
PDF only: Changes the TOC item identified by its index. Change the item title, destination, appearance (color, bold, italic) or collapsing sub-items – or to remove the item altogether.
Use this method if you need specific changes for selected entries only and want to avoid replacing the complete TOC. This is beneficial especially when dealing with large table of contents.

Parameters

• idx (int) – the index of the entry in the list created by Document.get_toc().
• dest_dict (dict) – the new destination. A dictionary like the last entry of an item in doc.get_toc(False). Using this as a template is recommended. When given, all other parameters are ignored – except title.
• kind (int) – the link kind, see Link Destination Kinds. If LINK_NONE, then all remaining parameter will be ignored, and the TOC item will be removed – same as Document.del_toc_item(). If None, then only the title is modified and the remaining parameters are ignored. All other values will lead to making a new destination dictionary using the subsequent arguments.
• pno (int) – the 1-based page number, i.e. a value 1 <= pno <= doc.page_count. Required for LINK_GOTO.
• uri (str) – the URL text. Required for LINK_URI.
• title (str) – the desired new title. None if no change.
• to (point_like) – (optional) points to a coordinate on the arget page. Relevant for LINK_GOTO. If omitted, a point near the page’s top is chosen.
• filename (str) – required for LINK_GOTOR and LINK_LAUNCH.
• zoom (float) – use this zoom factor when showing the target page.

Example use: Change the TOC of the SWIG manual to achieve this:
Collapse everything below top level and show the chapter on Python support in red, bold and italic:
>>> import fitz
>>> doc = fitz.open("SWIGDocumentation.pdf")
>>> toc = doc.get_toc(False)  # we need the detailed TOC
>>> # make a list of level 1 indices and their titles
>>> lvl1 = [(i, item[1]) for i, item in enumerate(toc) if item[0] == 1]
>>> for i, title in lvl1:
    d = toc[i][3]  # get the destination dict
    d["collapse"] = True  # collapse items underneath
    if "Python" in title:  # show the 'Python' chapter
        d["color"] = (1, 0, 0)  # in red,
        d["bold"] = True  # bold and
        d["italic"] = True  # italic
    doc.set_toc_item(i, dest_dict=d)  # update this toc item

In the previous example, we have changed only 42 of the 1240 TOC items of the file.

can_save_incrementally()
(New in version 1.16.0)

Check whether the document can be saved incrementally. Use it to choose the right option without en-
countering exceptions.

scrub(attached_files=True, clean_pages=True, embedded_files=True, hidden_text=True, javascript=True, metadata=True, redactions=True, redact_images=0, remove_links=True, reset_fields=True, reset_responses=True, thumbnails=True, xml_metadata=True)

PDF only: (New in v1.16.14) Remove potentially sensitive data from the PDF. This function is inspired
by the similar “Sanitize” function in Adobe Acrobat products. The process is configurable by a number
of options, which are all True by default.

Parameters

- **attached_files**(bool) – Search for ‘FileAttachment’ annotations and remove
  the file content.

- **clean_pages**(bool) – Remove any comments from page painting sources. If this
  option is set to False, then this is also done for hidden_text and redactions.

- **embedded_files**(bool) – Remove embedded files.

- **hidden_text**(bool) – Remove OCR-ed text and invisible text.

- **javascript**(bool) – Remove JavaScript sources.

- **metadata**(bool) – Remove PDF standard metadata.

- **redactions**(bool) – Apply redaction annotations.

- **redact_images**(int) – how to handle images if applying redactions. One of 0
  (ignore), 1 (blank out overlaps) or 2 (remove).

- **remove_links**(bool) – Remove all links.

- **reset_fields**(bool) – Reset all form fields to their defaults.

- **reset_responses**(bool) – Remove all responses from all annotations.

- **thumbnails**(bool) – Remove thumbnail images from pages.

- **xml_metadata**(bool) – Remove XML metadata.
save (outfile, garbage=0, clean=False, deflate=False, deflate_images=False, deflate_fonts=False, incremental=False, ascii=False, expand=0, linear=False, pretty=False, encryption=PDF_ENCRYPT_NONE, permissions=-1, owner_pw=None, user_pw=None)

(Changed in v1.18.7)

PDF only: Saves the document in its current state.

Parameters

- **outfile (str, Path, fp)** – The file path, `pathlib.Path` or file object to save to. A file object must have been created before via `open(...) or io.BytesIO()`. Choosing `io.BytesIO()` is similar to `Document.tobytes()` below, which equals the `getvalue()` output of an internally created `io.BytesIO()`.

- **garbage (int)** – Do garbage collection. Positive values exclude “incremental”.
  - 0 = none
  - 1 = remove unused (unreferenced) objects.
  - 2 = in addition to 1, compact the `xref` table.
  - 3 = in addition to 2, merge duplicate objects.
  - 4 = in addition to 3, check `stream` objects for duplication. This may be slow because such data are typically large.

- **clean (bool)** – Clean and sanitize content streams\(^1\). Corresponds to “multool clean -sc”.

- **deflate (bool)** – Deflate (compress) uncompressed streams.

- **deflate_images (bool)** – (new in v1.18.3) Deflate (compress) uncompressed image streams\(^4\).

- **deflate_fonts (bool)** – (new in v1.18.3) Deflate (compress) uncompressed fontfile streams\(^4\).

- **incremental (bool)** – Only save changes to the PDF. Excludes “garbage” and “linear”. Can only be used if `outfile` is a string or a `pathlib.Path` and equal to `Document.name`. Cannot be used for files that are decrypted or repaired and also in some other cases. To be sure, check `Document.can_save_incrementally()` If this is false, saving to a new file is required.

- **ascii (bool)** – convert binary data to ASCII.

- **expand (int)** – Decompress objects. Generates versions that can be better read by some other programs and will lead to larger files.
  - 0 = none
  - 1 = images
  - 2 = fonts
  - 255 = all

- **linear (bool)** – Save a linearised version of the document. This option creates a file format for improved performance for Internet access. Excludes “incremental”.

\(^1\) Content streams describe what (e.g. text or images) appears where and how on a page. PDF uses a specialized mini language similar to PostScript to do this (pp. 985 in *Adobe PDF References*), which gets interpreted when a page is loaded.

\(^4\) These parameters cause separate handling of stream categories: use it together with `expand` to restrict decompression to streams other than images / fontfiles.
• **pretty** *(bool)* – Prettyfy the document source for better readability. PDF objects will be reformatted to look like the default output of *Document.xref_object()*.

• **permissions** *(int)* – *(new in version 1.16.0)* Set the desired permission levels. See *Document Permissions* for possible values. Default is granting all.

• **encryption** *(int)* – *(new in version 1.16.0)* set the desired encryption method. See *PDF encryption method codes* for possible values.

• **owner_pw** *(str)* – *(new in version 1.16.0)* set the document’s owner password. *(Changed in v1.18.3)* If not provided, the user password is taken if provided.

• **user_pw** *(str)* – *(new in version 1.16.0)* set the document’s user password.

**saveIncr()**

PDF only: saves the document incrementally. This is a convenience abbreviation for *doc.save(doc.name, incremental=True, encryption=PDF_ENCRYPT_KEEP)*.

**tobytes** *(garbage=0, clean=False, deflate=False, deflate_images=False, deflate_fonts=False, ascii=False, expand=0, linear=False, pretty=False, encryption=PDF_ENCRYPT_NONE, permissions=-1, owner_pw=None, user_pw=None)*

*(Changed in v1.18.7)*

PDF only: Writes the *current content of the document* to a bytes object instead of to a file. Obviously, you should be wary about memory requirements. The meanings of the parameters exactly equal those in *save()*.

*(Changed in version 1.16.0)* for extended encryption support.

**Return type** bytes

**Returns** a bytes object containing the complete document.

**search_page_for** *(pno, text, quads=False)*

Search for “text” on page number “pno”. Works exactly like the corresponding *Page.search_for()*.

Any integer -inf < pno < page_count is acceptable.

**insert_pdf** *(docsr, from_page=-1, to_page=-1, start_at=-1, rotate=-1, links=True, annots=True, show_progress=0, final=1)*

PDF only: Copy the page range *[from_page, to_page]* (including both) of PDF document *docsr* into the current one. Inserts will start with page number *start_at*. Value -1 indicates default values. All pages thus copied will be rotated as specified. Links and annotations can be excluded in the target, see below. All page numbers are 0-based.

**Parameters**

• **docsr** *(Document)* – An opened PDF *Document* which must not be the current document. However, it may refer to the same underlying file.

• **from_page** *(int)* – First page number in *docsr*. Default is zero.

• **to_page** *(int)* – Last page number in *docsr* to copy. Defaults to last page.

• **start_at** *(int)* – First copied page, will become page number *start_at* in the target. Default -1 appends the page range to the end. If zero, the page range will be inserted before current first page.

• **rotate** *(int)* – All copied pages will be rotated by the provided value (degrees, integer multiple of 90).

• **links** *(bool)* – Choose whether (internal and external) links should be included in the copy. Default is True. Internal links to outside the copied page range are always excluded.
• **annots** *(bool) – (new in version 1.16.1)* choose whether annotations should be included in the copy.

• **show_progress** *(int) – (new in version 1.17.7)* specify an interval size greater than zero to see progress messages on *sys.stdout*. After each interval, a message like ```Inserted 30 of 47 pages.``` will be printed.

• **final** *(int) – (new in v1.18.0)* controls whether the list of already copied objects should be **dropped** after this method, default **True**. Set it to 0 except for the last one of multiple insertions from the same source PDF. This saves target file size and speeds up execution considerably.

**Note:**

1. If ```from_page > to_page``` pages will be **copied in reverse order**. If ```0 <= from_page == to_page``` then one page will be copied.

2. *docsrc* TOC entries will not be **copied**. It is easy however, to recover a table of contents for the resulting document. Look at the examples below and at program *PDFjoiner.py* in the *examples* directory: it can join PDF documents and at the same time piece together respective parts of the tables of contents.

```new_page(pno=-1, width=595, height=842)```
PDF only: Insert an empty page.

**Parameters**

• **pno** *(int)* – page number in front of which the new page should be inserted. Must be in ```1 < pno <= page_count``` Special values -1 and ```doc.page_count``` insert **after** the last page.

• **width** *(float)* – page width.

• **height** *(float)* – page height.

**Return type** *Page*

**Returns** the created page object.

```insert_page(pno, text=None, fontsize=11, width=595, height=842, fontname="helv", fontfile=None, color=None)```
PDF only: Insert a new page and insert some text. Convenience function which combines Document. new_page() and (parts of) Page.insertText().

**Parameters**

• **pno** *(int)* – page number (0-based) **in front of which** to insert. Must be in ```range(-1, len(doc) + 1)``` Special values -1 and ```len(doc)``` insert **after** the last page.

**Changed in version 1.14.12** This is now a positional parameter

For the other parameters, please consult the aforementioned methods.

**Return type** *int*

**Returns** the result of Page.insertText() (number of successfully inserted lines).

```delete_page(pno=-1)```
PDF only: Delete a page given by its 0-based number in ```-inf < pno < page_count - 1```.

**Changed in version 1.14.17**

**Parameters**

• **pno** *(int)* – the page to be deleted. Negative number count backwards from the end of the document (like with indices). Default is the last page.
**delete_pages** *(from_page=-1, to_page=-1)*

PDF only: Delete a range of pages given as 0-based numbers. Any -1 parameter will first be replaced by `doc.page_count - 1` (ie. last page number). After that, condition `0 <= from_page <= to_page < doc.page_count` must be true. If the parameters are equal, this is equivalent to `delete_page()`.

**Parameters**
- `from_page` *(int)* – the first page to be deleted.
- `to_page` *(int)* – the last page to be deleted.

**Note:** *(Changed in v1.14.17, optimized in v1.17.7)* In an effort to maintain a valid PDF structure, this method and `delete_page()` will also invalidate items in the table of contents which happen to point to deleted pages. “Invalidation” here means, that the bookmark will point to nowhere and the title will show the string “<>”. So the overall TOC structure is left intact.

Similarly, it will remove any links on remaining pages that point to a deleted page. This action may have an extended response time for documents with many pages.

Example: Delete the page range 500 to 520 from a large PDF, using different methods.

**Method 1 - delete_pages:**

```python
import time, fitz
doc = fitz.open("Adobe PDF Reference 1-7.pdf")
t0=time.perf_counter();doc.delete_pages(500, 520);t1=time.perf_counter()
round(t1 - t0, 2)
0.66
```

**Method 2 - select**, this is more than 10 times slower:

```python
l = list(range(500)) + list(range(521, 1310))
t0=time.perf_counter();doc.select(l);t1=time.perf_counter()
round(t1 - t0, 2)
7.62
```

**copy_page** *(pno, to=-1)*

PDF only: Copy a page reference within the document.

**Parameters**
- `pno` *(int)* – the page to be copied. Must be in range `0 <= pno < len(doc)`.
- `to` *(int)* – the page number in front of which to copy. The default inserts after the last page.

**Note:** Only a new reference to the page object will be created – not a new page object, all copied pages will have identical attribute values, including the `Page.xref`. This implies that any changes to one of these copies will appear on all of them.

**fullcopy_page** *(pno, to=-1)*

*(New in version 1.14.17)*

PDF only: Make a full copy (duplicate) of a page.

**Parameters**
- `pno` *(int)* – the page to be duplicated. Must be in range `0 <= pno < len(doc)`.
• **to (int)** – the page number in front of which to copy. The default inserts after the last page.

**Note:**
- In contrast to `copyPage()`, this method creates a new page object (with a new `xref`), which can be changed independently from the original.
- Any Popup and “IRT” (“in response to”) annotations are **not copied** to avoid potentially incorrect situations.

**move_page** *(pno, to=-1)*  
PDF only: Move (copy and then delete original) a page within the document.

**Parameters**
- **pno (int)** – the page to be moved. Must be in range \(0 \leq pno < \text{len}(doc)\).
- **to (int)** – the page number in front of which to insert the moved page. The default moves after the last page.

**need_appearances** *(value=None)*  
*(New in v1.17.4)*
PDF only: Get or set the `/NeedAppearances` property of Form PDFs. Quote: “*(Optional) A flag specifying whether to construct appearance streams and appearance dictionaries for all widget annotations in the document... Default value: false.*” This may help controlling the behavior of some readers / viewers.

**Parameters**
- **value (bool)** – set the property to this value. If omitted or `None`, inquire the current value.

**Return type** bool

**Returns**
- None: not a Form PDF or property not defined.
- True / False: the value of the property (either just set or existing for inquiries).

Once set, the property cannot be removed again (which is no problem).

**get_sigflags** *
PDF only: Return whether the document contains signature fields. This is an optional PDF property: if not present (return value -1), no conclusions can be drawn – the PDF creator may just not have bothered to use it.

**Return type** int

**Returns**
- -1: not a Form PDF / no signature fields recorded / no `SigFlags` found.
- 1: at least one signature field exists.
- 3: contains signatures that may be invalidated if the file is saved (written) in a way that alters its previous contents, as opposed to an incremental update.

**embfile_add** *(name, buffer, filename=None, ufilename=None, desc=None)*  
PDF only: Embed a new file. All string parameters except the name may be unicode (in previous versions, only ASCII worked correctly). File contents will be compressed (where beneficial).

**Changed in version 1.14.16** The sequence of positional parameters “name” and “buffer” has been changed to comply with the layout of other functions.
Parameters

- **name** *(str)* – entry identifier, must not already exist.
- **buffer** *(bytes, bytearray, BytesIO)* – file contents.
  
  *(Changed in version 1.14.13)* `io.BytesIO` is now also supported.
- **filename** *(str)* – optional filename. Documentation only, will be set to `name` if `None`.
- **ufilename** *(str)* – optional unicode filename. Documentation only, will be set to `filename` if `None`.
- **desc** *(str)* – optional description. Documentation only, will be set to `name` if `None`.

**embfile_count()**

PDF only: Return the number of embedded files.

*Changed in version 1.14.16* This is now a method. In previous versions, this was a property.

**embfile_get** *(item)*

PDF only: Retrieve the content of embedded file by its entry number or name. If the document is not a PDF, or entry cannot be found, an exception is raised.

**Parameters**

- **item** *(int, str)* – index or name of entry. An integer must be in `range(embfile_count())`.

**Return type** bytes

**embfile_del** *(item)*

PDF only: Remove an entry from `/EmbeddedFiles`. As always, physical deletion of the embedded file content (and file space regain) will occur only when the document is saved to a new file with a suitable garbage option.

*Changed in version 1.14.16* Items can now be deleted by index, too.

**Parameters**

- **item** *(int/str)* – index or name of entry.

**Warning:** When specifying an entry name, this function will only delete the first item with that name. Be aware that PDFs not created with PyMuPDF may contain duplicate names. So you may want to take appropriate precautions.

**embfile_info** *(item)*

PDF only: Retrieve information of an embedded file given by its number or by its name.

**Parameters**

- **item** *(int/str)* – index or name of entry. An integer must be in `range(embfile_count())`.

**Return type** dict

**Returns**

- a dictionary with the following keys:
  
  - **name** *(str)* name under which this entry is stored
  - **filename** *(str)* filename
  - **ufilename** *(unicode)* filename
  - **desc** *(str)* description
- size – (int) original file size
- length – (int) compressed file length

embfile_names()
(New in version 1.14.16)

PDF only: Return a list of embedded file names. The sequence of names equals the physical sequence in
the document.

**Return type** list

embfile_upd(item, buffer=None, filename=None, ufilename=None, desc=None)

PDF only: Change an embedded file given its entry number or name. All parameters are optional. Letting
them default leads to a no-operation.

**Parameters**

- item (int/str) – index or name of entry. An integer must be in range(0, embfile_count()).
- buffer (bytes, bytearray, BytesIO) – the new file content.
  (Changed in version 1.14.13) io.BytesIO is now also supported.
- filename (str) – the new filename.
- ufilename (str) – the new unicode filename.
- desc (str) – the new description.

embfile_setinfo(n, filename=None, ufilename=None, desc=None)

PDF only: Change embedded file meta information. All parameters are optional. Letting them default
will lead to a no-operation.

**Parameters**

- n (int,str) – index or name of entry. An integer must be in range(embfile_count()).
- filename (str) – sets the filename.
- ufilename (str) – sets the unicode filename.
- desc (str) – sets the description.

**Note:** Deprecated subset of **embfile_upd().** Will be deleted in a future version.

close()

Release objects and space allocations associated with the document. If created from a file, also closes
filename (releasing control to the OS).

xref_object(xref, compressed=False, ascii=False)
(New in version 1.16.8)

PDF only: Return the definition source of a PDF object.

pdf_catalog()
(New in version 1.16.8)

PDF only: Return the xref number of the PDF catalog (or root) object. Use that number with
Document.xref_object() to see its source.

pdf_trailer(compressed=False)
(New in version 1.16.8)
PDF only: Return the trailer source of the PDF (UTF-8), which is usually located at the PDF file’s end. This is similar to `Document.xref_object()` except that this object has no identifier to access it.

```python
xref_xml_metadata()
(\textit{New in version 1.16.8})
```

PDF only: Return the \texttt{xref} of the document’s XML metadata.

```python
xref_stream(xref)
(\textit{New in version 1.16.8})
```

PDF only: Return the \texttt{decompressed} contents of the \texttt{xref} stream object.

**Parameters**

- \texttt{xref \texttt{int}} – \texttt{xref} number.

**Return type**

\texttt{bytes}

**Returns**

the (decompressed) stream of the object.

```python
xref_stream_raw(xref)
(\textit{New in version 1.16.8})
```

PDF only: Return the \texttt{unmodified} (esp. \texttt{not decompressed}) contents of the \texttt{xref} stream object. Otherwise equal to `Document.xref_stream()`.

**Return type**

\texttt{bytes}

**Returns**

the (original, unmodified) stream of the object.

```python
update_object(xref, obj_str, page=None)
(\textit{New in version 1.16.8})
```

PDF only: Replace object definition of \texttt{xref} with the provided string. The \texttt{xref} may also be new, in which case this instruction completes the object definition. If a page object is also given, its links and annotations will be reloaded afterwards.

**Parameters**

- \texttt{xref \texttt{int}} – \texttt{xref} number.
- \texttt{obj\_str \texttt{str}} – a string containing a valid PDF object definition.
- \texttt{page \texttt{Page}} – a page object. If provided, indicates, that annotations of this page should be refreshed (reloaded) to reflect changes incurred with links and / or annotations.

**Return type**

\texttt{int}

**Returns**

zero if successful, otherwise an exception will be raised.

```python
update_stream(xref, data, new=False)
(\textit{New in version 1.14.13:})
```

Replace the stream of an object identified by \texttt{xref}. If the object has no stream, an exception is raised unless \texttt{new=True} is used. The function automatically performs a compress operation (“\texttt{deflate}”) where beneficial.

**Parameters**

- \texttt{xref \texttt{int}} – \texttt{xref} number.
- \texttt{stream \texttt{bytes|bytearray|BytesIO}} – the new content of the stream.

\textit{(Changed in version 1.14.13:)} \texttt{io.BytesIO} objects are now also supported.
new (bool) – whether to force accepting the stream, and thus turning it into a stream object.

Caution: The object of xref must be a PDF dictionary for this to work, and especially must not be empty – as is the case if you just created the xref via Document.get_new_xref(). To avoid this, execute doc.update_object(xref, "<<>>") before inserting the stream.

This method is intended to manipulate streams containing PDF operator syntax (see pp. 985 of the Adobe PDF References) as it is the case for e.g. page content streams.

If you update a contents stream, you should use save parameter clean=True. This ensures consistency between PDF operator source and the object structure.

Example: Let us assume that you no longer want a certain image appear on a page. This can be achieved by deleting the respective reference in its contents source(s) – and indeed: the image will be gone after reloading the page. But the page’s resources object would still show the image as being referenced by the page. This save option will clean up any such mismatches.

has_links ()

has_annots ()

subset_fonts ()

PDF only: Check whether there are links, resp. annotations anywhere in the document.

Returns True / False. As opposed to fields, which are stored in a central place of a PDF document, the existence of links / annotations can only be detected by parsing each page. These methods are tuned to do this efficiently and will immediately return, if the answer is True for a page. For PDFs with many thousand pages however, an answer may take some time if no link, resp. no annotation is found.

PDF only: Investigate eligible fonts for their use by text in the document. If a font is supported and a size reduction is possible, a subset of that font is built with a reduced character set, and the respective text is rewritten.

Use this method immediately before saving the document. The following features and restrictions apply for the time being:

- Package fontTools must be installed. It is required for creating the font subsets.
- Supported font types include only embedded OTF, TTF and WOFF that are not already subsets.
- The script directory must be available for writing temporary files during the subsetting process.
- All text using a subsetted font will be rewritten. Under typical circumstances this should lead to an identical appearance, but the following deviations are possible:
  - Individual, by-character spacing is ignored, and resp. text is written with spacing as determined by the font.
  - Rewritten text will always be visible: any previous restrictions like hidden text, optional content text, etc. are ignored.

6 For a False the complete document must be scanned. Both methods do not load pages, but only scan object definitions. This makes them at least 10 times faster than application-level loops (where total response time roughly equals the time for loading all pages). For the Adobe PDF References (1’310 pages) and the Pandas documentation (over 3’070 pages) – both have no annotations – the method needs about 11 ms for the answer False. So response times will probably become significant only well beyond this order of magnitude.
The greatest benefit can probably achieved when creating new PDFs using large fonts. In these cases the amount of text is typically relatively small. Using this feature can reduce the embedded font by more than 95% easily.

**outline**
Contains the first *Outline* entry of the document (or *None*). Can be used as a starting point to walk through all outline items. Accessing this property for encrypted, not authenticated documents will raise an `AttributeError`.

**is_closed**
*False* if document is still open. If closed, most other attributes and methods will have been deleted / disabled. In addition, *Page* objects referring to this document (i.e. created with `Document.load_page()`) and their dependent objects will no longer be usable. For reference purposes, `Document.name` still exists and will contain the filename of the original document (if applicable).

**is_dirty**
*True* if this is a PDF document and contains unsaved changes, else *False*.

**is_pdf**
*True* if this is a PDF document, else *False*.

**is_form_pdf**
*False* if this is not a PDF or has no form fields, otherwise the number of root form fields (fields with no ancestors).

*(Changed in version 1.16.4)* Returns the total number of (root) form fields.

**is_reflowable**
*True* if document has a variable page layout (like e-books or HTML). In this case you can set the desired page dimensions during document creation (open) or via method `layout()`.

**is_repaired**
*(New in v1.18.2)*
*True* if PDF has been repaired during open (because of major structure issues). Always *False* for non-PDF documents. If true, more details have been stored in `TOOLS.mupdf_warnings()`, and `Document.can_save_incrementally()` will return *False*.

**needs_pass**
Indicates whether the document is password-protected against access. This indicator remains unchanged – even after the document has been authenticated. Precludes incremental saves if true.
is_encrypted
This indicator initially equals Document.needs_pass. After successful authentication, it is set to False to reflect the situation.

Type bool

permissions
Contains the permissions to access the document. This is an integer containing bool values in respective bit positions. For example, if doc.permissions & fitz.PDF_PERM_MODIFY > 0, you may change the document. See Document Permissions for details.

Changed in version 1.16.0 This is now an integer comprised of bit indicators. Was a dictionary previously.

Type int

metadata
Contains the document’s meta data as a Python dictionary or None (if is_encrypted=True and needPass=True). Keys are format, encryption, title, author, subject, keywords, creator, producer, creationDate, modDate, /Title, /Author, /Subject, /Trapped and /Keywords respectively.

- format contains the document format (e.g. ‘PDF-1.6’, ‘XPS’, ‘EPUB’).
- encryption either contains None (no encryption), or a string naming an encryption method (e.g. ‘Standard V4 R4 128-bit RC4’). Note that an encryption method may be specified even if needsPass=False. In such cases not all permissions will probably have been granted. Check Document.permissions for details.
- If the date fields contain valid data (which need not be the case at all!), they are strings in the PDF-specific timestamp format “D:<TS><TZ>”, where
  - <TS> is the 12 character ISO timestamp YYYYMMDDhhmmss (YYYY - year, MM - month, DD - day, hh - hour, mm - minute, ss - second), and
  - <TZ> is a time zone value (time intervall relative to GMT) containing a sign (‘+’ or ‘-’), the hour (hh), and the minute (‘mm’, note the apostrophies!).
- A Paraguayan value might hence look like D:20150415131602-04'00’, which corresponds to the timestamp April 15, 2015, at 1:16:02 pm local time Asuncion.

Type dict

name
Contains the filename or filetype value with which Document was created.

Type str

page_count
Contains the number of pages of the document. May return 0 for documents with no pages. Function len(doc) will also deliver this result.

Type int

chapter_count
(New in version 1.17.0) Contains the number of chapters in the document. Always at least 1. Relevant only for document types with chapter support (EPUB currently). Other documents will return 1.

Type int
last_location

(New in version 1.17.0) Contains (chapter, pno) of the document’s last page. Relevant only for document types with chapter support (EPUB currently). Other documents will return (0, len(doc) - 1) and (0, -1) if it has no pages.

Type int

FormFonts

A list of form field font names defined in the /AcroForm object. None if not a PDF.

Type list

Note: For methods that change the structure of a PDF (insert_pdf(), select(), copyPage(), delete_page() and others), be aware that objects or properties in your program may have been invalidated or orphaned. Examples are Page objects and their children (links, annotations, widgets), variables holding old page counts, tables of content and the like. Remember to keep such variables up to date or delete orphaned objects. Also refer to Ensuring Consistency of Important Objects in PyMuPDF.

6.4.1 set_metadata() Example

Clear metadata information. If you do this out of privacy / data protection concerns, make sure you save the document as a new file with garbage > 0. Only then the old /Info object will also be physically removed from the file. In this case, you may also want to clear any XML metadata inserted by several PDF editors:

```python
>>> import fitz

>>> doc = fitz.open("pymupdf.pdf")

>>> doc.metadata  # look at what we currently have
{'producer': 'rst2pdf, reportlab', 'format': 'PDF 1.4', 'encryption': None, 'author': 'Jorj X. McKie', 'modDate': "D:20160611145816-04'00'", 'keywords': 'PDF, XPS, EPUB, CBZ', 'title': 'The PyMuPDF Documentation', 'creationDate': "D:20160611145816-04'00'", 'creator': 'sphinx', 'subject': 'PyMuPDF 1.9.1'}

>>> doc.set_metadata({})  # clear all fields

>>> doc.metadata  # look again to show what happened
{'producer': 'none', 'format': 'PDF 1.4', 'encryption': None, 'author': 'none', 'modDate': 'none', 'keywords': 'none', 'title': 'none', 'creationDate': 'none', 'creator': 'none', 'subject': 'none'}

>>> doc._delXmlMetadata()  # clear any XML metadata

>>> doc.save("anonymous.pdf", garbage = 4)  # save anonymized doc
```

6.4.2 set_toc() Demonstration

This shows how to modify or add a table of contents. Also have a look at csv2toc.py and toc2csv.py in the examples directory.

```python
>>> import fitz

>>> doc = fitz.open("test.pdf")

>>> toc = doc.get_toc()

>>> for t in toc: print(t)  # show what we have
[1, 'The PyMuPDF Documentation', 1]
[2, 'Introduction', 1]
[3, 'Note on the Name fitz', 1]
[3, 'License', 1]
```

(continues on next page)
6.4.3 insert_pdf() Examples

(1) Concatenate two documents including their TOCs:

```python
>>> doc1 = fitz.open("file1.pdf")  # must be a PDF
>>> doc2 = fitz.open("file2.pdf")  # must be a PDF
>>> pages1 = len(doc1)  # save doc1's page count
>>> toc1 = doc1.get_toc(False)  # save TOC 1
>>> toc2 = doc2.get_toc(False)  # save TOC 2
>>> doc1.insert_pdf(doc2)  # doc2 at end of doc1
>>> for t in doc.get_toc(): print(t)  # increase toc2 page numbers
    [1, 'The PyMuPDF Documentation', 1]
    [2, 'Introduction modified by set_toc', 1]  # <<< this has changed
    [3, 'Note on the Name fitz', 1]
    [3, 'License', 1]
```

Obviously, similar ways can be found in more general situations. Just make sure that hierarchy levels in a row do not increase by more than one. Inserting dummy bookmarks before and after toc2 segments would heal such cases. A ready-to-use GUI (wxPython) solution can be found in script PDFjoiner.py of the examples directory.

(2) More examples:

```python
>>> # insert 5 pages of doc2, where its page 21 becomes page 15 in doc1
>>> doc1.insert_pdf(doc2, from_page=21, to_page=25, start_at=15)

>>> # same example, but pages are rotated and copied in reverse order
>>> doc1.insert_pdf(doc2, from_page=25, to_page=21, start_at=15, rotate=90)

>>> # put copied pages in front of doc1
>>> doc1.insert_pdf(doc2, from_page=21, to_page=25, start_at=0)
```

6.4.4 Other Examples

Extract all page-referenced images of a PDF into separate PNG files:

```python
for i in range(len(doc)):
    imglist = doc.get_page_images(i)
    for img in imglist:
        xref = img[0]  # xref number
        pix = fitz.Pixmap(doc, xref)  # make pixmap from image
        if pix.n - pix.alpha < 4:  # can be saved as PNG
            pix.writePNG("p%s-%s.png" % (i, xref))
        else:  # CMYK: must convert first
            pix0 = fitz.Pixmap(fitz.csRGB, pix)
            pix0.writePNG("p%s-%s.png" % (i, xref))
```
Rotate all pages of a PDF:

```python
>>> for page in doc: page.set_rotation(90)
```

## 6.5 Font

*(New in v1.16.18)* This class represents a font as defined in MuPDF (`fz_font_s` structure). It is required for the new class `TextWriter` and the new `Page.write_text()` method. Currently, it has no connection to how fonts are used in methods `Page.insert_text()` or `Page.insert_textbox()`, respectively.

A Font object also contains useful general information, like the font bbox, the number of defined glyphs, glyph names or the bbox of a single glyph.

<table>
<thead>
<tr>
<th>Method / Attribute</th>

### Class API

```python
class Font

    __init__(self, fontname=None, fontfile=None, fontbuffer=None, script=0, language=None, ordering=-1, is_bold=0, is_italic=0, is_serif=0)

Font constructor. The large number of parameters are used to locate font, which most closely resembles the requirements. Not all parameters are ever required – see the below pseudo code explaining the logic how the parameters are evaluated.

### Parameters

- **fontname (str)** – one of the *PDF Base 14 Fonts* or CJK fontnames. Also possible are a select few other names like (watch the correct spelling): “Arial”, “Times”, “Times Roman”. *(Changed in v1.17.5)*
If you have installed pymupdf-fonts, there are also new “reserved” fontnames available, which are listed in fitz_fonts and in the table further down.

- **filename (str)** – the filename of a fontfile somewhere on your system\(^1\).
- **fontbuffer (bytes, bytearray, io.BytesIO)** – a fontfile loaded in memory\(^1\).
- **script (int)** – the number of a UCDN script. Currently supported in PyMuPDF are numbers 24, and 32 through 35.
- **language (str)** – one of the values “zh-Hant” (traditional Chinese), “zh-Hans” (simplified Chinese), “ja” (Japanese) and “ko” (Korean). Otherwise, all ISO 639 codes from the subsets 1, 2, 3 and 5 are also possible, but are currently documentary only.
- **ordering (int)** – an alternative selector for one of the CJK fonts.
- **is_bold (bool)** – look for a bold font.
- **is_italic (bool)** – look for an italic font.
- **is_serif (bool)** – look for a serifed font.

**Returns**
a MuPDF font if successful. This is the overall sequence of checks to determine an appropriate font:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>fontfile?</td>
<td>Create font from file, exception if failure.</td>
</tr>
<tr>
<td>fontbuffer?</td>
<td>Create font from buffer, exception if failure.</td>
</tr>
<tr>
<td>ordering&gt;=0</td>
<td>Create universal font, always succeeds.</td>
</tr>
<tr>
<td>fontname?</td>
<td>Create a Base-14 font, universal font, or font provided by pymupdf-fonts. See table below.</td>
</tr>
</tbody>
</table>

**Note:** With the usual reserved names “helv”, “tiro”, etc., you will create fonts with the expected names “Helvetica”, “Times-Roman” and so on. **However**, and in contrast to `Page.insertFont()` and friends,

- a font file will always be embedded in your PDF,
- Greek and Cyrillic characters are supported without needing the `encoding` parameter.

Using `ordering >= 0`, or fontnames “cjk”, “china-t”, “china-s”, “japan” or “korea” will always create the same “universal” font “Droid Sans Fallback Regular”. This font supports all CJK and all Latin characters, including Greek and Cyrillic.

Actually, you would rarely ever need another font than “Droid Sans Fallback Regular”. **Except** that this font file is relatively large and adds about 1.65 MB (compressed) to your PDF file size. If you do not need CJK support, stick with specifying “helv”, “tiro” etc., and you will get away with about 35 KB compressed.

\(^1\) MuPDF does not support all fontfiles with this feature and will raise exceptions like “mupdf: FT_New_Memory_Face((null)): unknown file format”, if it encounters issues.
If you know you have a mixture of CJK and Latin text, consider just using \texttt{Font("cjk")} because this supports everything and also significantly (by a factor of two to three) speeds up execution: MuPDF will always find any character in this single font and need not check fallbacks.

But if you do specify a Base-14 fontname, you will still be able to also write CJK characters: MuPDF detects this situation and silently falls back to the universal font (which will then of course also be embedded in your PDF).

\textit{(New in v1.17.5)} Optionally, some new “reserved” fontname codes become available if you install \texttt{pymupdf-fonts}. “Fira Mono” is a nice mono-spaced sans font set and \texttt{FiraGO} is another non-serifed “universal” font, set which supports all Latin (including Cyrillic and Greek) plus Thai, Arabian, Hebrew and Devanagari – but none of the CJK languages. The size of a FiraGO font is only a quarter of the “Droid Sans Fallback” size (compressed 400 KB vs. 1.65 MB) – and it provides the weight bold, italic, bold-italic – which the universal font doesn’t.

“Space Mono” is another nice and small mono-spaced font from Google Fonts, which supports Latin Extended characters and comes with all 4 important weights.

The following table maps a fontname code to the corresponding font:

<table>
<thead>
<tr>
<th>Code</th>
<th>Fontname</th>
<th>New in</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>figo</td>
<td>FiraGO Regular</td>
<td>v1.0.0</td>
<td>narrower than Helvetica</td>

</tr>
</tbody>
</table>

\texttt{has_glyph}(\texttt{chr}, \texttt{language}=None, \texttt{script}=0, \texttt{fallback}=False)

Check whether the unicode \texttt{chr} exists in the font or some fallback font. May be used to check whether any “TOFU” symbols will appear on output.

\textbf{Parameters}

- \texttt{chr (int)} – the unicode of the character (i.e. \texttt{ord()}).
- \texttt{language (str)} – the language – currently unused.
- \texttt{script (int)} – the UCDN script number.
- \texttt{fallback (bool)} – (new in v1.17.5) perform an extended search in fallback fonts or restrict to current font (default).

\textbf{Returns} (changed in 1.17.7) the glyph number. Zero indicates no glyph found.
**valid_codepoints()**

*(New in v1.17.5)*

Return an array of unicodes supported by this font.

**Returns**

an `array.array`\(^2\) of length at most `Font.glyph_count`. I.e. `chr()` of every item in this array has a glyph in the font without using fallbacks. This is an example display of the supported glyphs:

```python
>>> import fitz
>>> font = fitz.Font("math")
>>> vuc = font.valid_codepoints()
>>> for i in vuc:
...     print("%04X %s (%s)" % (i, chr(i), font.unicode_to_glyph_name(i)))
0000 (CR)
0020 (space)
0021 ! (exclam)
0022 " (quotedbl)
0023 # (numbersign)
0024 $ (dollar)
0025 % (percent)
...
21D0 (arrowdblleft)
21D1 (arrowdblup)
21D2 (arrowdbright)
21D3 (arrowdbldown)
21D4 (arrowdblboth)
...
221E ∞ (infinity)
```

**Note:** This method only returns meaningful data for fonts having a CMAP (character map, charmap, the /ToUnicode PDF key). Otherwise, this array will have length 1 and contain zero only.

**glyph_advance** *(chr, language=None, script=0, wmode=0)*

Calculate the “width” of the character’s glyph (visual representation).

**Parameters**

- **chr** *(int)* – the unicode number of the character. Use `ord()`, not the character itself. Again, this should normally work even if a character is not supported by that font, because fallback fonts will be checked where necessary.

- **wmode** *(int)* – write mode, 0 = horizontal, 1 = vertical.

The other parameters are not in use currently.

**Returns** a float representing the glyph’s width relative to `fontsize 1`.

\(^2\) The built-in module `array` has been chosen for its speed and its compact representation of values.
**glyph_name_to_unicode** *(name)*

Return the unicode value for a given glyph name. Use it in conjunction with *chr()* if you want to output e.g. a certain symbol.

**Parameters**
- *name* (*str*) – The name of the glyph.

**Returns**

The unicode integer, or 65533 = 0xFFFD if the name is unknown. Examples:
- `font.glyph_name_to_unicode("Sigma") = 931`
- `font.glyph_name_to_unicode("sigma") = 963`

Refer to the Adobe Glyph List publication for a list of glyph names and their unicode numbers. Example:

```python
>>> font = fitz.Font("helv")
>>> font.has_glyph(font.glyph_name_to_unicode("infinity"))
True
```

**glyph_bbox** *(chr, language=None, script=0)*

The glyph rectangle relative to fontsize 1.

**Parameters**
- *chr* (*int*) – *ord()* of the character.

**Returns**

A *Rect*.

**unicode_to_glyph_name** *(ch)*

Show the name of the character’s glyph.

**Parameters**
- *ch* (*int*) – the unicode number of the character. Use *ord()* , not the character itself.

**Returns**

A string representing the glyph’s name. E.g. `font.glyph_name(ord("#")) = "numbersign"`. For an invalid code “.notfound” is returned.

**Note:** *(Changed in v1.18.0)* This method and *Font.glyph_name_to_unicode()* no longer depend on a font and instead retrieve information from the Adobe Glyph List. Also available as *fitz.unicode_to_glyph_name()* and resp. *fitz.glyph_name_to_unicode()*.

**text_length** *(text, fontsize=11)*

Calculate the length of a unicode string.

**Parameters**

- *text* (*str*) – a text string – UTF-8 encoded. For Python 2, you must use unicode here.
- *fontsize* (*float*) – the fontsize.

**Return type**

*float*

**Returns**

The length of the string when stored in the PDF. Internally *glyph_advance()* is used on a by-character level. If the font does not have a character, it will automatically be looked up in a fallback font.

**buffer** *(New in v1.17.6)*

Copy of the binary font file content.

**Return type**

*bytes*
flags
A dictionary with various font properties, each represented as bools. Example for Helvetica:

```python
>>> pprint(font.flags)
{'bold': 0,
 'fake-bold': 0,
 'fake-italic': 0,
 'invalid-bbox': 0,
 'italic': 0,
 'mono': 0,
 'opentype': 0,
 'serif': 1,
 'stretch': 0,
 'substitute': 0}
```

Return type dict

name
Return type str

Name of the font. May be “” or “(null)”.

bbox
The font bbox. This is the maximum of its glyph bboxes.

Return type Rect

glyph_count
Return type int

The number of glyphs defined in the font.

ascender
(New in v1.18.0)

The ascender value of the font, see here for details.

Return type float

descender
(New in v1.18.0)

The descender value of the font, see here for details.

Return type float

isWritable
(New in v1.18.0)

Indicates whether this font can be used with TextWriter.

Return type bool

6.6 Identity

Identity is a Matrix that performs no action – to be used whenever the syntax requires a matrix, but no actual transformation should take place. It has the form fitz.Matrix(1, 0, 0, 1, 0, 0).

Identity is a constant, an “immutable” object. So, all of its matrix properties are read-only and its methods are disabled.
If you need a mutable identity matrix as a starting point, use one of the following statements:

```python
>>> m = fitz.Matrix(1, 0, 0, 1, 0, 0)  # specify the values
>>> m = fitz.Matrix(1, 1)           # use scaling by factor 1
>>> m = fitz.Matrix(0)              # use rotation by zero degrees
>>> m = fitz.Matrix(fitz.Identity)  # make a copy of Identity
```

## 6.7 IRect

IRect is a rectangular bounding box similar to `Rect`, except that all corner coordinates are integers. IRect is used to specify an area of pixels, e.g. to receive image data during rendering. Otherwise, many similarities exist, e.g. considerations concerning emptiness and finiteness of rectangles also apply to this class.

<table>
<thead>
<tr>

</tr>
<tr>
<td><code>IRect.x1</code></td>
<td>X-coordinate of the bottom right corner</td>
</tr>
<tr>
<td><code>IRect.y0</code></td>
<td>Y-coordinate of the top left corner</td>
</tr>
<tr>
<td><code>IRect.y1</code></td>
<td>Y-coordinate of the bottom right corner</td>
</tr>
</tbody>
</table>

### Class API

```python
class IRect

    __init__(self)
    __init__(self, x0, y0, x1, y1)
    __init__(self, irect)
    __init__(self, sequence)
```

Overloaded constructors. Also see examples below and those for the `Rect` class.

If another irect is specified, a new copy will be made.
If sequence is specified, it must be a Python sequence type of 4 numbers (see Using Python Sequences as Arguments in PyMuPDF). Non-integer numbers will be truncated, non-numeric entries will raise an exception.

The other parameters mean integer coordinates.

**getRect()**
A convenience function returning a Rect with the same coordinates. Also available as attribute `rect`.

Return type Rect

**getRectArea([unit])**

**getArea([unit])**
Calculates the area of the rectangle and, with no parameter, equals `abs(IRect)`. Like an empty rectangle, the area of an infinite rectangle is also zero.

Parameters unit `str` – Specify required unit: respective squares of “px” (pixels, default), “in” (inches), “cm” (centimeters), or “mm” (millimeters).

Return type float

**intersect(ir)**
The intersection (common rectangular area) of the current rectangle and `ir` is calculated and replaces the current rectangle. If either rectangle is empty, the result is also empty. If either rectangle is infinite, the other one is taken as the result – and hence also infinite if both rectangles were infinite.

Parameters ir `rect_like` – Second rectangle.

**contains(x)**
Checks whether `x` is contained in the rectangle. It may be `rect_like, point_like` or a number. If `x` is an empty rectangle, this is always true. Conversely, if the rectangle is empty this is always False, if `x` is not an empty rectangle and not a number. If `x` is a number, it will be checked to be one of the four components. `x in irect and irect.contains(x)` are equivalent.

Parameters x `IRect or Rect or Point or int` – the object to check.

Return type bool

**intersects(r)**
Checks whether the rectangle and the `rect_like` “r” contain a common non-empty `IRect`. This will always be False if either is infinite or empty.

Parameters r `rect_like` – the rectangle to check.

Return type bool

**morph(fixpoint, matrix)**
(New in version 1.17.0)
Return a new quad after applying a matrix to it using a fixed point.

Parameters
- fixpoint `point_like` – the fixed point.
- matrix `matrix_like` – the matrix.

Returns a new Quad. This a wrapper of the same-named quad method.

**norm()**
(New in version 1.16.0)
Return the Euclidean norm of the rectangle treated as a vector of four numbers.
normalize()
Make the rectangle finite. This is done by shuffling rectangle corners. After this, the bottom right corner will indeed be south-eastern to the top left one. See Rect for a more details.

top_left
tl
Equals Point(x0, y0).
Type Point
top_right
tr
Equals Point(x1, y0).
Type Point
bottom_left
bl
Equals Point(x0, y1).
Type Point
bottom_right
br
Equals Point(x1, y1).
Type Point
quad
The quadrilateral Quad(irect.tl, irect.tr, irect.bl, irect.br).
Type Quad
width
Contains the width of the bounding box. Equals abs(x1 - x0).
Type int
height
Contains the height of the bounding box. Equals abs(y1 - y0).
Type int
x0
X-coordinate of the left corners.
Type int
y0
Y-coordinate of the top corners.
Type int
x1
X-coordinate of the right corners.
Type int
y1
Y-coordinate of the bottom corners.
Type int
**isInfinite**

True if rectangle is infinite, False otherwise.

Type bool

**isEmpty**

True if rectangle is empty, False otherwise.

Type bool

---

**Note:**

- This class adheres to the Python sequence protocol, so components can be accessed via their index, too. Also refer to *Using Python Sequences as Arguments in PyMuPDF*.
- Rectangles can be used with arithmetic operators – see chapter *Operator Algebra for Geometry Objects*.

---

### 6.8 Link

Represents a pointer to somewhere (this document, other documents, the internet). Links exist per document page, and they are forward-chained to each other, starting from an initial link which is accessible by the `Page.firstLink` property.

There is a parent-child relationship between a link and its page. If the page object becomes unusable (closed document, any document structure change, etc.), then so does every of its existing link objects – an exception is raised saying that the object is “orphaned”, whenever a link property or method is accessed.

<table>
<thead>
<tr>

</tr>
<tr>
<td><code>Link.uri</code></td>
<td>link destination</td>
</tr>
<tr>
<td><code>Link.xref</code></td>
<td>xref number of the entry</td>
</tr>
</tbody>
</table>

**Class API**

class Link

**setBorder** *(border=None, width=0, style=None, dashes=None)*

PDF only: Change border width and dashing properties.

*(Changed in version 1.16.9)* Allow specification without using a dictionary. The direct parameters are used if `border` is not a dictionary.

**Parameters**

- `border` *(dict)* – a dictionary as returned by the `border` property, with keys “width” *(float)*, “style” *(str)* and “dashes” *(sequence)*. Omitted keys will leave the resp. property unchanged. To e.g. remove dash use: “dashes”: [] . If dashes is not an empty sequence, “style” will automatically be set to “D” (dashed).
• **width** *(float)* – see above.
• **style** *(str)* – see above.
• **dashes** *(sequence)* – see above.

**setColors** *(colors=None, stroke=None, fill=None)*
Changes the “stroke” and “fill” colors.

*(Changed in version 1.16.9)* Allow colors to be directly set. These parameters are used if *colors* is not a dictionary.

**Parameters**

- **colors** *(dict)* – a dictionary containing color specifications. For accepted dictionary keys and values see below. The most practical way should be to first make a copy of the *colors* property and then modify this dictionary as required.
- **stroke** *(sequence)* – see above.
- **fill** *(sequence)* – see above.

**colors**
Meaningful for PDF only: A dictionary of two lists of floats in range 0 <= float <= 1 specifying the *stroke* and the interior (*fill*) colors. If not a PDF, *None* is returned. The stroke color is used for borders and everything that is actively painted or written (“stroked”). The lengths of these lists implicitly determine the colorspace used: 1 = GRAY, 3 = RGB, 4 = CMYK. So [1.0, 0.0, 0.0] stands for RGB color red. Both lists can be [] if no color is specified. The value of each float *f* is mapped to the integer value *i* in range 0 to 255 via the computation *f* = *i* / 255.

**Return type**  dict

**border**
Meaningful for PDF only: A dictionary containing border characteristics. It will be *None* for non-PDFs and an empty dictionary if no border information exists. The following keys can occur:

- **width** – a float indicating the border thickness in points. The value is -1.0 if no width is specified.
- **dashes** – a sequence of integers specifying a line dash pattern. [] means no dashes, [n] means equal on-off lengths of *n* points, longer lists will be interpreted as specifying alternating on-off length values. See the *Adobe PDF References* page 217 for more details.
- **style** – 1-byte border style: S (Solid) = solid rectangle surrounding the annotation, D (Dashed) = dashed rectangle surrounding the link, the dash pattern is specified by the *dashes* entry, B (Beveled) = a simulated embossed rectangle that appears to be raised above the surface of the page, I (Inset) = a simulated engraved rectangle that appears to be recessed below the surface of the page, U (Underline) = a single line along the bottom of the annotation rectangle.

**Return type**  dict

**rect**
The area that can be clicked in untransformed coordinates.

**Type**  Rect

**isExternal**
A bool specifying whether the link target is outside of the current document.

**Type**  bool

**uri**
A string specifying the link target. The meaning of this property should be evaluated in conjunction with property *isExternal*. The value may be *None*, in which case *isExternal* == False. If *uri* starts with file://,
mailto:, or an internet resource name, \texttt{isExternal} is \texttt{True}. In all other cases \texttt{isExternal} == \texttt{False} and \texttt{uri} points to an internal location. In case of PDF documents, this should either be \texttt{#nnnn} to indicate a 1-based (!) page number \texttt{nnn}, or a named location. The format varies for other document types, e.g. \texttt{uri = `/FixedDoc.fdoc#PG_2_LNK_1`} for page number \texttt{2} (1-based) in an XPS document.

\begin{description}
\item[Type] \texttt{str}
\item[xref] An integer specifying the PDF \texttt{xref}. Zero if not a PDF.
\item[next] The next link or \texttt{None}.
\item[dest] The link destination details object.
\end{description}

### 6.9 linkDest

Class representing the \texttt{dest} property of an outline entry or a link. Describes the destination to which such entries point.

```
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Short Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linkDest.dest</td>
<td>destination</td>
</tr>
<tr>
<td>linkDest.fileSpec</td>
<td>file specification (path, filename)</td>
</tr>
<tr>
<td>linkDest.flags</td>
<td>descriptive flags</td>
</tr>
<tr>
<td>linkDest.isMap</td>
<td>is this a MAP?</td>
</tr>
<tr>
<td>linkDest.isUri</td>
<td>is this a URI?</td>
</tr>
<tr>
<td>linkDest.kind</td>
<td>kind of destination</td>
</tr>
<tr>
<td>linkDest.lt</td>
<td>top left coordinates</td>
</tr>
<tr>
<td>linkDest.named</td>
<td>name if named destination</td>
</tr>
<tr>
<td>linkDest.newWindow</td>
<td>name of new window</td>
</tr>
<tr>
<td>linkDest.page</td>
<td>page number</td>
</tr>
<tr>
<td>linkDest.rb</td>
<td>bottom right coordinates</td>
</tr>
<tr>
<td>linkDest.uri</td>
<td>URI</td>
</tr>
</tbody>
</table>
```

Class API

```
class linkDest

dest

Target destination name if \texttt{linkDest.kind} is \texttt{LINK_GOTOR} and \texttt{linkDest.page} is \texttt{-1}.

Type \texttt{str}

fileSpec

Contains the filename and path this link points to, if \texttt{linkDest.kind} is \texttt{LINK_GOTOR} or \texttt{LINK_LAUNCH}.

Type \texttt{str}
```
flags
A bitfield describing the validity and meaning of the different aspects of the destination. As far as possible, link destinations are constructed such that e.g. `linkDest.lt` and `linkDest.rb` can be treated as defining a bounding box. But the flags indicate which of the values were actually specified, see Link Destination Flags.

Type int

isMap
This flag specifies whether to track the mouse position when the URI is resolved. Default value: False.

Type bool

isUri
Specifies whether this destination is an internet resource (as opposed to e.g. a local file specification in URI format).

Type bool

kind
Indicates the type of this destination, like a place in this document, a URI, a file launch, an action or a place in another file. Look at Link Destination Kinds to see the names and numerical values.

Type int

lt
The top left Point of the destination.

Type Point

named
This destination refers to some named action to perform (e.g. a javascript, see Adobe PDF References). Standard actions provided are NextPage, PrevPage, FirstPage, and LastPage.

Type str

newWindow
If true, the destination should be launched in a new window.

Type bool

page
The page number (in this or the target document) this destination points to. Only set if `linkDest.kind` is LINK_GOTOR or LINK_GOTO. May be -1 if `linkDest.kind` is LINK_GOTOR. In this case `linkDest.dest` contains the name of a destination in the target document.

Type int

rb
The bottom right Point of this destination.

Type Point

uri
The name of the URI this destination points to.

Type str

6.10 Matrix

Matrix is a row-major 3x3 matrix used by image transformations in MuPDF (which complies with the respective concepts laid down in the Adobe PDF References). With matrices you can manipulate the rendered image of a page
in a variety of ways: (parts of) the page can be rotated, zoomed, flipped, sheared and shifted by setting some or all of just six float values.

Since all points or pixels live in a two-dimensional space, one column vector of that matrix is a constant unit vector, and only the remaining six elements are used for manipulations. These six elements are usually represented by \([a, b, c, d, e, f]\). Here is how they are positioned in the matrix:

\[
\begin{bmatrix}
  a & b & 0 \\
  c & d & 0 \\
  e & f & 1
\end{bmatrix}
\]

Please note:

- the below methods are just convenience functions – everything they do, can also be achieved by directly manipulating the six numerical values
- all manipulations can be combined – you can construct a matrix that rotates **and** shears **and** scales **and** shifts, etc. in one go. If you however choose to do this, do have a look at the **remarks** further down or at the Adobe PDF References.

<table>
<thead>
<tr>

<td>horizontal shift</td>
</tr>
<tr>
<td>Matrix.f</td>
<td>vertical shift</td>
</tr>
<tr>
<td>Matrix.isRectilinear</td>
<td>true if rect corners will remain rect corners</td>
</tr>
</tbody>
</table>

Class API

```python
class Matrix

    __init__(self)
    __init__(self, zoom-x, zoom-y)
    __init__(self, shear-x, shear-y, l)
    __init__(self, a, b, c, d, e, f)
    __init__(self, matrix)
    __init__(self, degree)
```
__init__(self, sequence)

Overloaded constructors.

Without parameters, the zero matrix $\begin{bmatrix} 0.0 & 0.0 & 0.0 & 0.0 & 0.0 & 0.0 \end{bmatrix}$ will be created.

`zoom-*` and `shear-*` specify zoom or shear values (float) and create a zoom or shear matrix, respectively.

For “matrix” a new copy of another matrix will be made.

Float value “degree” specifies the creation of a rotation matrix which rotates anti-clockwise.

A “sequence” must be any Python sequence object with exactly 6 float entries (see Using Python Sequences as Arguments in PyMuPDF).

$\text{fitz.Matrix}(1, 1)$, $\text{fitz.Matrix}(0.0)$ and $\text{fitz.Matrix}(\text{fitz.Identity})$ create modifyable versions of the Identity matrix, which looks like $[1, 0, 0, 1, 0, 0]$.

(norm)

(New in version 1.16.0)

Return the Euclidean norm of the matrix as a vector.

preRotate(deg)

Modify the matrix to perform a counter-clockwise rotation for positive deg degrees, else clockwise. The matrix elements of an identity matrix will change in the following way:

$[1, 0, 0, 1, 0, 0] \rightarrow [\cos(deg), \sin(deg), -\sin(deg), \cos(deg), 0, 0]$

Parameters

- **deg (float)** – The rotation angle in degrees (use conventional notation based on $\pi = 180$ degrees).

preScale(xx, yy)

Modify the matrix to scale by the zoom factors sx and sy. Has effects on attributes $a$ thru $d$ only: $[a, b, c, d, e, f] \rightarrow [a*xx, b*xx, c*sy, d*sy, e, f]$.

Parameters

- **sx (float)** – Zoom factor in X direction. For the effect see description of attribute $a$.
- **sy (float)** – Zoom factor in Y direction. For the effect see description of attribute $d$.

preShear(xx, yy)

Modify the matrix to perform a shearing, i.e. transformation of rectangles into parallelograms (rhomboids). Has effects on attributes $a$ thru $d$ only: $[a, b, c, d, e, f] \rightarrow [c*sy, d*sy, a*xx, b*xx, e, f]$.

Parameters

- **sx (float)** – Shearing effect in X direction. See attribute $c$.
- **sy (float)** – Shearing effect in Y direction. See attribute $b$.

preTranslate(tx, ty)

Modify the matrix to perform a shifting / translation operation along the x and / or y axis. Has effects on attributes $e$ and $f$ only: $[a, b, c, d, e, f] \rightarrow [c*sy, d*sy, a*xx, b*xx, e, f]$.

Parameters

- **tx (float)** – Translation effect in X direction. See attribute $e$.
- **ty (float)** – Translation effect in Y direction. See attribute $f$.

concat(m1, m2)

Calculate the matrix product $m1 * m2$ and store the result in the current matrix. Any of $m1$ or $m2$ may be
the current matrix. Be aware that matrix multiplication is not commutative. So the sequence of \( m_1, m_2 \) is important.

**Parameters**

- \( m_1 \) ([Matrix]) – First (left) matrix.
- \( m_2 \) ([Matrix]) – Second (right) matrix.

**invert** \((m = \text{None})\)

Calculate the matrix inverse of \( m \) and store the result in the current matrix. Returns 1 if \( m \) is not invertible ("degenerate"). In this case the current matrix will not change. Returns 0 if \( m \) is invertible, and the current matrix is replaced with the inverted \( m \).

**Parameters** \( m \) ([Matrix]) – Matrix to be inverted. If not provided, the current matrix will be used.

**Return type** int

**a**

Scaling in X-direction ([width]). For example, a value of 0.5 performs a shrink of the width by a factor of 2. If \( a < 0 \), a left-right flip will (additionally) occur.

**Type** float

**b**

Causes a shearing effect: each \( \text{Point}(x, y) \) will become \( \text{Point}(x, y - b*x) \). Therefore, looking from left to right, e.g. horizontal lines will be “tilt” – downwards if \( b > 0 \), upwards otherwise (\( b \) is the tangens of the tilting angle).

**Type** float

**c**

Causes a shearing effect: each \( \text{Point}(x, y) \) will become \( \text{Point}(x - c*y, y) \). Therefore, looking upwards, vertical lines will be “tilt” – to the left if \( c > 0 \), to the right otherwise (\( c \) ist the tangens of the tilting angle).

**Type** float

**d**

Scaling in Y-direction ([height]). For example, a value of 1.5 performs a stretch of the height by 50%. If \( d < 0 \), an up-down flip will (additionally) occur.

**Type** float

**e**

Causes a horizontal shift effect: Each \( \text{Point}(x, y) \) will become \( \text{Point}(x + e, y) \). Positive (negative) values of \( e \) will shift right (left).

**Type** float

**f**

Causes a vertical shift effect: Each \( \text{Point}(x, y) \) will become \( \text{Point}(x, y - f) \). Positive (negative) values of \( f \) will shift down (up).

**Type** float

**isRectilinear**

Rectilinear means that no shearing is present and that any rotations are integer multiples of 90 degrees. Usually this is used to confirm that (axis-aligned) rectangles before the transformation are still axis-aligned rectangles afterwards.

**Type** bool
Note:

- This class adheres to the Python sequence protocol, so components can be accessed via their index, too. Also refer to Using Python Sequences as Arguments in PyMuPDF.
- A matrix can be used with arithmetic operators – see chapter Operator Algebra for Geometry Objects.
- Changes of matrix properties and execution of matrix methods can be executed consecutively. This is the same as multiplying the respective matrices.
- Matrix multiplication is not commutative – changing the execution sequence in general changes the result. So it can quickly become unclear which result a transformation will yield.

To keep results foreseeable for a series of matrix operations, Adobe recommends the following approach (Adobe PDF References, page 206):

1. Shift (“translate”)
2. Rotate
3. Scale or shear (“skew”)

### 6.10.1 Examples

Here are examples to illustrate some of the effects achievable. The following pictures start with a page of the PDF version of this help file. We show what happens when a matrix is being applied (though always full pages are created, only parts are displayed here to save space).

This is the original page image:

---

6.10.2 Shifting

We transform it with a matrix where \( e = 100 \) (right shift by 100 pixels).
Next we do a down shift by 100 pixels: $f = 100$.

### 6.10.3 Flipping

Flip the page left-right ($a = -1$).
6.10.4 Shearing

First a shear in Y direction \((b = 0.5)\).
Second a shear in X direction ($c = 0.5$).

Finally a rotation by 30 clockwise degrees ($preRotate(-30)$).
6.11 Outline

`outline` (or “bookmark”), is a property of `Document`. If not `None`, it stands for the first outline item of the document. Its properties in turn define the characteristics of this item and also point to other outline items in “horizontal” or downward direction. The full tree of all outline items for e.g. a conventional table of contents (TOC) can be recovered by following these “pointers”.
<table>

Class API

class Outline

down
   The next outline item on the next level down. Is None if the item has no kids.

   Type Outline

next
   The next outline item at the same level as this item. Is None if this is the last one in its level.

   Type Outline

page
   The page number (0-based) this bookmark points to.

   Type int

title
   The item’s title as a string or None.

   Type str

is_open
   Or isOpen – an indicator showing whether any sub-outlines should be expanded (True) or be collapsed (False). This information should be interpreted by PDF display software accordingly.

   Type bool

isExternal
   A bool specifying whether the target is outside (True) of the current document.

   Type bool

uri
   A string specifying the link target. The meaning of this property should be evaluated in conjunction with isExternal. The value may be None, in which case isExternal == False. If uri starts with file://, mailto:, or an internet resource name, isExternal is True. In all other cases isExternal == False and uri points to an internal location. In case of PDF documents, this should either be #nnnn to indicate a 1-based (!) page number nnnn, or a named location. The format varies for other document types, e.g. uri = ‘.//FixedDoc.fdoc#PG_21_LNK_84’ for page number 21 (1-based) in an XPS document.

   Type str

dest
   The link destination details object.

   Type linkDest
6.12 Page

Class representing a document page. A page object is created by `Document.load_page()` or, equivalently, via indexing the document like `doc[n]` - it has no independent constructor.

There is a parent-child relationship between a document and its pages. If the document is closed or deleted, all page objects (and their respective children, too) in existence will become unusable (“orphaned”): If a page property or method is being used, an exception is raised.

Several page methods have a `Document` counterpart for convenience. At the end of this chapter you will find a synopsis.

6.12.1 Modifying Pages

Changing page properties and adding or changing page content is available for PDF documents only.

In a nutshell, this is what you can do with PyMuPDF:

- Modify page rotation and the visible part (“cropbox”) of the page.
- Insert images, other PDF pages, text and simple geometrical objects.
- Add annotations and form fields.

Note: Methods require coordinates (points, rectangles) to put content in desired places. Please be aware that since v1.17.0 these coordinates must always be provided relative to the unrotated page. The reverse is also true: except `Page.rect`, resp. `Page.bound()` (both reflect when the page is rotated), all coordinates returned by methods and attributes pertain to the unrotated page.

So the returned value of e.g. `Page.getImageBbox()` will not change if you do a `Page.set_rotation()`. The same is true for coordinates returned by `Page.getText()`, annotation rectangles, and so on. If you want to find out, where an object is located in rotated coordinates, multiply the coordinates with `Page.rotationMatrix`. There also is its inverse, `Page.derotationMatrix`, which you can use when interfacing with other readers, which may behave differently in this respect.

Note: If you add or update annotations, links or form fields on the page and immediately afterwards need to work with them (i.e. without leaving the page), you should reload the page using `Document.reload_page()` before referring to these new or updated items.

This ensures all your changes have been fully applied to PDF structures, so can safely create Pixmaps or successfully iterate over annotations, links and form fields.

Class API

class Page

bound()

Determine the rectangle of the page. Same as property `Page.rect` below. For PDF documents this usually also coincides with `mediabox` and `cropbox`, but not always. For example, if the page is rotated, then this is reflected by this method – the `Page.cropbox` however will not change.

Return type `Rect`

addCaretAnnot(point)

(New in version 1.16.0)

PDF only: Add a caret icon. A caret annotation is a visual symbol normally used to indicate the presence of text edits on the page.

Parameters

point (point_like) – the top left point of a 20 x 20 rectangle containing the MuPDF-provided icon.

Return type `Annot`

Returns the created annotation.

'Caret' annotation

addTextAnnot(point, text, icon="Note")

PDF only: Add a comment icon ("sticky note") with accompanying text. Only the icon is visible, the accompanying text is hidden and can be visualized by many PDF viewers by hovering the mouse over the symbol.

Parameters
• **point** (*point_like*) – the top left point of a 20 x 20 rectangle containing the MuPDF-provided “note” icon.

• **text** (*str*) – the commentary text. This will be shown on double clicking or hovering over the icon. May contain any Latin characters.

• **icon** (*str*) – *(new in version 1.16.0)* choose one of “Note” (default), “Comment”, “Help”, “Insert”, “Key”, “NewParagraph”, “Paragraph” as the visual symbol for the embodied text.⁴

**Return type**: **Annot**

**Returns** the created annotation.

```python
addFreetextAnnot(rect, text, fontsize=12, fontname="helv", text_color=0, fill_color=1, rotate=0, align=TEXT_ALIGN_LEFT)
```

PDF only: Add text in a given rectangle.

**Parameters**

• **rect** (*rect_like*) – the rectangle into which the text should be inserted. Text is automatically wrapped to a new line at box width. Lines not fitting into the box will be invisible.

• **text** (*str*) – the text. *(New in v1.17.0)* May contain any mixture of Latin, Greek, Cyrillic, Chinese, Japanese and Korean characters. The respective required font is automatically determined.

• **fontsize** (*float*) – the font size. Default is 12.

• **fontname** (*str*) – the font name. Default is “Helv”. Accepted alternatives are “Cour”, “TiRo”, “ZaDb” and “Symb”. The name may be abbreviated to the first two characters, like “Co” for “Cour”. Lower case is also accepted. *(Changed in v1.16.0)* Bold or italic variants of the fonts are no longer accepted. A user-contributed script provides a circumvention for this restriction – see section Using Buttons and JavaScript in chapter Collection of Recipes. *(New in v1.17.0)* The actual font to use is now determined on a by-character level, and all required fonts (or sub-fonts) are automatically included. Therefore, you should rarely ever need to care about this parameter and let it default (except you insist on a serified font for your non-CJK text parts).

• **text_color** (*sequence, float*) – *(new in version 1.16.0)* the text color. Default is black.

• **fill_color** (*sequence, float*) – *(new in version 1.16.0)* the fill color. Default is white.

• **align** (*int*) – *(new in version 1.17.0)* text alignment, one of TEXT_ALIGN_LEFT, TEXT_ALIGN_CENTER, TEXT_ALIGN_RIGHT - justify is not supported.

• **rotate** (*int*) – the text orientation. Accepted values are 0, 90, 270, invalid entries are set to zero.

**Return type**: **Annot**

**Returns** the created annotation. Color properties can only be changed using special parameters of Annot.update(). There, you can also set a border color different from the text color.

```python
addFileAnnot(pos, buffer, filename, ufilename=None, desc=None, icon="PushPin")
```

PDF only: Add a file attachment annotation with a “PushPin” icon at the specified location.

⁴ You are generally free to choose any of the Annotation Icons in MuPDF you consider adequate.
Parameters

- **pos** *(point_like)* – the top-left point of a 18x18 rectangle containing the MuPDF-provided “PushPin” icon.
- **buffer** *(bytes, bytearray, BytesIO)* – the data to be stored (actual file content, any data, etc.).
  
  Changed in version 1.14.13. `io.BytesIO` is now also supported.
- **filename** *(str)* – the filename to associate with the data.
- **ufilename** *(str)* – the optional PDF unicode version of filename. Defaults to filename.
- **desc** *(str)* – an optional description of the file. Defaults to filename.
- **icon** *(str)* – *(new in version 1.16.0)* choose one of “PushPin” (default), “Graph”, “Paperclip”, “Tag” as the visual symbol for the attached data.

Return type: `Annot`

Returns the created annotation. Use methods of `Annot` to make any changes.

`addInkAnnot` *(list)*

PDF only: Add a “freehand” scribble annotation.

Parameters **list** *(sequence)* – a list of one or more lists, each containing `point_like` items. Each item in these sublists is interpreted as a `Point` through which a connecting line is drawn. Separate sublists thus represent separate drawing lines.

Return type: `Annot`

Returns the created annotation in default appearance (black line of width 1). Use annotation methods with a subsequent `Annot.update()` to modify.

`addLineAnnot` *(p1, p2)*

PDF only: Add a line annotation.

Parameters

- **p1** *(point_like)* – the starting point of the line.
- **p2** *(point_like)* – the end point of the line.

Return type: `Annot`

Returns the created annotation. It is drawn with line color black and line width 1. The rectangle is automatically created to contain both points, each one surrounded by a circle of radius 3 * line width to make room for any line end symbols.

`addRectAnnot` *(rect)*

`addCircleAnnot` *(rect)*

PDF only: Add a rectangle, resp. circle annotation.

Parameters **rect** *(rect_like)* – the rectangle in which the circle or rectangle is drawn, must be finite and not empty. If the rectangle is not equal-sided, an ellipse is drawn.

Return type: `Annot`

Returns the created annotation. It is drawn with line color red, no fill color and line width 1.

`addRedactAnnot` *(quad, text=None, fontname=None, fontsize=11, align=TEXT_ALIGN_LEFT, fill=(1, 1, 1), text_color=(0, 0, 0), cross_out=True)*

PDF only: *(new in version 1.16.11)* Add a redaction annotation. A redaction annotation identifies content
to be removed from the document. Adding such an annotation is the first of two steps. It makes visible what will be removed in the subsequent step, `Page.apply_redactions()`.

**Parameters**

- **quad**(quad_like, rect_like) – specifies the (rectangular) area to be removed which is always equal to the annotation rectangle. This may be a rect_like or quad_like object. If a quad is specified, then the envelopping rectangle is taken.

- **text**(str) – *(New in v1.16.12)* text to be placed in the rectangle after applying the redaction (and thus removing old content).

- **fontname**(str) – *(New in v1.16.12)* the font to use when text is given, otherwise ignored. The same rules apply as for `Page.insert_textbox()` – which is the method `Page.apply_redactions()` internally invokes. The replacement text will be vertically centered, if this is one of the CJK or PDF Base 14 Fonts.

**Note:**

- For an existing font of the page, use its reference name as fontname (this is item[4] of its entry in `Page.get_fonts()`).

- For a new, non-built-in font, proceed as follows:

```python
page.insert_text(point,  # anywhere, but outside all
    "somthing",  # some non-empty string
    fontname="newname",  # new, unused reference name
    fontfile="...",  # desired font file
    render_mode=3,  # makes the text invisible
)  # can also be page.addRedactAnnot(..., fontname="newname")
```

- **fontsize**(float) – *(New in v1.16.12)* the fontsize to use for the replacing text. If the text is too large to fit, several insertion attempts will be made, gradually reducing the fontsize to no less than 4. If then the text will still not fit, no text insertion will take place at all.

- **align**(int) – *(New in v1.16.12)* the horizontal alignment for the replacing text. See `insert_textbox()` for available values. The vertical alignment is (approximately) centered if a PDF built-in font is used (CJK or PDF Base 14 Fonts).

- **fill**(sequence) – *(New in v1.16.12)* the fill color of the rectangle after applying the redaction. The default is white = (1, 1, 1), which is also taken if None is specified. *(Changed in v1.16.13)* To suppress a fill color altogether, specify False. In this cases the rectangle remains transparent.

- **text_color**(sequence) – *(New in v1.16.12)* the color of the replacing text. Default is black = (0, 0, 0).

- **cross_out**(bool) – *(new in v1.17.2)* add two diagonal lines to the annotation rectangle.

**Return type** Annot

**Returns** the created annotation. *(Changed in v1.17.2)* Its standard appearance looks like a red rectangle (no fill color), optionally showing two diagonal lines. Colors, line width, dashing, opacity and blend mode can now be set and applied via Annot.update() like with other annotations.
addPolylineAnnot(points)

addPolygonAnnot(points)

PDF only: Add an annotation consisting of lines which connect the given points. A Polygon’s first and last points are automatically connected, which does not happen for a PolyLine. The rectangle is automatically created as the smallest rectangle containing the points, each one surrounded by a circle of radius 3 (= 3 * line width). The following shows a ‘PolyLine’ that has been modified with colors and line ends.

Parameters points(list) – a list of point_like objects.

Return type Annot

Returns the created annotation. It is drawn with line color black, no fill color and line width 1. Use methods of Annot to make any changes to achieve something like this:

![PolyLine annotation](image)

addUnderlineAnnot(quads=None, start=None, stop=None, clip=None)

addStrikeoutAnnot(quads=None, start=None, stop=None, clip=None)

addSquigglyAnnot(quads=None, start=None, stop=None, clip=None)

addHighlightAnnot(quads=None, start=None, stop=None, clip=None)

PDF only: These annotations are normally used for marking text which has previously been somehow located (for example via Page.search_for()). But this is not required: you are free to “mark” just anything.

Standard colors are chosen per annotation type: yellow for highlighting, red for strike out, green for underlining, and magenta for wavy underlining.

The methods convert the arguments into a list of Quad objects. The annotation rectangle is then calculated to envelop all these quadrilaterals.

Note: search_for() delivers a list of either rectangles or quadrilaterals. Such a list can be directly used as an argument for these annotation types and will deliver one common annotation for all occurrences of the search string:

```python
>>> # always prefer quads=True in text searching!
>>> quads = page.search_for("pymupdf", quads=True)
>>> page.addHighlightAnnot(quads)
```

Note: Obviously, text marker annotations need to know what is the top and the bottom, the left and the right side of the tetragon to be marked. If the arguments are quads, this information is given by the sequence of the quad points. In contrast, a rectangle delivers much less information – this is illustrated by the fact, that 4! = 24 different quads can be constructed with the four corners of each reactangle.
Therefore, we **strongly recommend** to use the `quads` option for text searches, to ensure correct text markers. For more details on text marking see section “How to Mark Non-horizontal Text” of *Collection of Recipes*.

### Parameters

- **`quads` (rect_like, quad_like, list, tuple)** – *(Changed in v1.14.20)* the location(s) – rectangle(s) or quad(s) – to be marked. A list or tuple must consist of `rect_like` or `quad_like` items (or even a mixture of either). Every item must be finite, convex and not empty (as applicable). *(Changed in v1.16.14)* **Set this parameter to `None` if you want to use the following arguments.**

- **`start` (point_like)** – *(New in v1.16.14)* start text marking at this point. Defaults to the top-left point of `clip`.

- **`stop` (point_like)** – *(New in v1.16.14)* stop text marking at this point. Defaults to the bottom-right point of `clip`.

- **`clip` (rect_like)** – *(New in v1.16.14)* only consider text lines intersecting this area. Defaults to the page rectangle.

**Return type**: *Annot* or *(changed in v1.16.14) None*

**Returns**: the created annotation. *(Changed in v1.16.14)* If `quads` is an empty list, **no annotation** is created.

**Note**: Starting with v1.16.14 you can use parameters `start`, `stop` and `clip` to highlight consecutive lines between the points `start` and `stop`. Make use of `clip` to further reduce the selected line boxes and thus deal with e.g. multi-column pages. The following multi-line highlight on a page with three text columns was created by specifying the two red points and setting `clip` accordingly.

### addStampAnnot

PDF only: Add a “rubber stamp” like annotation to e.g. indicate the document’s intended use (“DRAFT”, “CONFIDENTIAL”, etc.).

#### Parameters

- **`rect` (rect_like)** – rectangle where to place the annotation.

- **`stamp` (int)** – id number of the stamp text. For available stamps see *Stamp Annotation Icons*.

**Note:**
• The stamp’s text and its border line will automatically be sized and be put horizontally and vertically centered in the given rectangle. `Annot.rect` is automatically calculated to fit the given `width` and will usually be smaller than this parameter.

• The font chosen is “Times Bold” and the text will be upper case.

• The appearance can be changed using `Annot.setOpacity()` and by setting the “stroke” color (no “fill” color supported).

• This can be used to create watermark images: on a temporary PDF page create a stamp annotation with a low opacity value, make a pixmap from it with `alpha=True` (and potentially also rotate it), discard the temporary PDF page and use the pixmap with `insert_image()` for your target PDF.

---

`addWidget(widget)`
PDF only: Add a PDF Form field (“widget”) to a page. This also turns the PDF into a Form PDF. Because of the large amount of different options available for widgets, we have developed a new class `Widget`, which contains the possible PDF field attributes. It must be used for both, form field creation and updates.

**Parameters** `widget` (`Widget`) – a `Widget` object which must have been created upfront.

**Returns** a widget annotation.

`delete_annot(annot)`
PDF only: Delete annotation from the page and return the next one.

Changed in version 1.16.6 The removal will now include any bound ‘Popup’ or response annotations and related objects.

**Parameters** `annot` (`Annot`) – the annotation to be deleted.

**Return type** `Annot`

**Returns** the annotation following the deleted one. Please remember that physical removal requires saving to a new file with garbage > 0.

`delete_widget(widget)`
(New in v1.18.4)
PDF only: Delete field from the page and return the next one.

**Parameters** `widget` (`Widget`) – the widget to be deleted.

**Return type** `Widget`

**Returns** the widget following the deleted one. Please remember that physical removal requires saving to a new file with garbage > 0.

`apply_redactions(images=PDF_REDACT_IMAGE_PIXELS)`
(New in version 1.16.11)
PDF only: Remove all text content contained in any redaction rectangle.

(Changed in v1.16.12) The previous `mark` parameter is gone. Instead, the respective rectangles are filled with the individual `fill` color of each redaction annotation. If a `text` was given in the annotation, then `insert_textbox()` is invoked to insert it, using parameters provided with the redaction.

This method applies and then deletes all redactions from the page.
Parameters `images` *(int)* *(new in v1.18.0)* how to redact overlapping images. The default *(2)* blanks out overlapping pixels. `PDF_REDACT_IMAGE_NONE` *(0)* ignores, and `PDF_REDACT_IMAGE_REMOVE` *(1)* completely removes all overlapping images.

**Returns** `True` if at least one redaction annotation has been processed, `False` otherwise.

**Note:** Text contained in a redaction rectangle will be physically removed from the page and will no longer appear in e.g. text extractions or anywhere else. Other annotations are unaffected.

All overlapping links will be removed.

 *(Changed in v1.18.0)* The overlapping parts of `images` will be blanked-out for option *(2)*. Option *(0)* does not touch any images and *(1)* will remove any image with an overlap.

Please be aware that there is an MuPDF bug for option `PDF_REDACT_IMAGE_PIXELS` *(2)*: transparent images will be incorrectly handled!

To remove only selected images (as opposed to all intersecting), use PyMuPDF low-level functions instead of redaction annotations.

Text removal is done by character: A character is removed if its bbox has a non-empty intersection with a redaction *(changed in MuPDF v1.17)*.

Redactions are an easy way to replace single words in a PDF, or to just physically remove them from the PDF: locate the word “secret” using some text extraction or search method and insert a redaction using “xxxxxx” as replacement text for each occurrence.

- Be wary if the replacement is longer than the original – this may lead to an awkward appearance, line breaks or no new text at all.
- For a number of reasons, the new text may not exactly be positioned on the same line like the old one – especially true if the replacement font was not one of CJK or PDF Base 14 Fonts.

### delete_link *(linkdict)*

PDF only: Delete the specified link from the page. The parameter must be an original item of `get_links()` *(see below)*. The reason for this is the dictionary’s “xref” key, which identifies the PDF object to be deleted.

**Parameters** `linkdict` *(dict)* – the link to be deleted.

### insert_link *(linkdict)*

PDF only: Insert a new link on this page. The parameter must be a dictionary of format as provided by `get_links()` *(see below)*.

**Parameters** `linkdict` *(dict)* – the link to be inserted.

### update_link *(linkdict)*

PDF only: Modify the specified link. The parameter must be a (modified) original item of `get_links()` *(see below)*. The reason for this is the dictionary’s “xref” key, which identifies the PDF object to be changed.

**Parameters** `linkdict` *(dict)* – the link to be modified.

### get_label ()

*(New in v1.18.6)*

PDF only: Return the label for the page.

**Return type** `str`

**Returns** the label string like “vii” for Roman numbering or “” if not defined.
get_links()
Retrieves all links of a page.

Return type list

Returns A list of dictionaries. For a description of the dictionary entries see below. Always use this or the Page.links() method if you intend to make changes to the links of a page.

links (kinds=None)
(New in version 1.16.4)
Return a generator over the page’s links. The results equal the entries of Page.get_links().

Parameters kinds (sequence) – a sequence of integers to down-select to one or more link kinds. Default is all links. Example: kinds=(fitz.LINK_GOTO,) will only return internal links.

Return type generator

Returns an entry of Page.get_links() for each iteration.

annots (types=None)
(New in version 1.16.4)
Return a generator over the page’s annotations.

Parameters types (sequence) – a sequence of integers to down-select to one or annotation types. Default is all annotations. Example: types=(fitz.PDF_ANNOT_FREETEXT, fitz.PDF_ANNOT_TEXT) will only return ‘FreeText’ and ‘Text’ annotations.

Return type generator

Returns an Annot for each iteration.

widgets (types=None)
(New in version 1.16.4)
Return a generator over the page’s form fields.

Parameters types (sequence) – a sequence of integers to down-select to one or more widget types. Default is all form fields. Example: types=(fitz.PDF_WIDGET_TYPE_TEXT,) will only return ‘Text’ fields.

Return type generator

Returns a Widget for each iteration.

write_text (rect=None, writers=None, overlay=True, color=None, opacity=None, keep_proportion=True, rotate=0, oc=0)
(New in version 1.16.18)
PDF only: Write the text of one or more TextWriter objects to the page.

Parameters

• rect (rect_like) – where to place the text. If omitted, the rectangle union of the text writers is used.

• writers (sequence) – a non-empty tuple / list of TextWriter objects or a single TextWriter.

• opacity (float) – set transparency, overwrites resp. value in the text writers.

• color (sequence) – set the text color, overwrites resp. value in the text writers.

• overlay (bool) – put the text in foreground or background.
• **keep_proportion** *(bool)* – maintain the aspect ratio.
• **rotate** *(float)* – rotate the text by an arbitrary angle.
• **oc** *(int)* – *(new in v1.18.4)* the `xref` of an OCG or OCMD.

**Note:** Parameters `overlay`, `keep_proportion`, `rotate` and `oc` have the same meaning as in `Page.show_pdf_page()`.

```python
insert_text(point, text, fontsize=11, fontname=”helv”, fontfile=None, idx=0, color=None, fill=None, render_mode=0, border_width=1, encoding=TEXT_ENCODING_LATIN, rotate=0, morph=None, stroke_opacity=1, fill_opacity=1, overlay=True, oc=0)
```

(Changed in v1.18.4)

PDF only: Insert text starting at `point_like point`. See `Shape.insert_text()`.

```python
insert_textbox(rect, buffer, fontsize=11, fontname=”helv”, fontfile=None, idx=0, color=None, fill=None, render_mode=0, border_width=1, encoding=TEXT_ENCODING_LATIN, expandtabs=8, align=TEXT_ALIGN_LEFT, charwidths=None, rotate=0, morph=None, stroke_opacity=1, fill_opacity=1, oc=0, overlay=True)
```

(Changed in v1.18.4)

PDF only: Insert text into the specified `rect_like rect`. See `Shape.insert_textbox()`.

```python
draw_line(p1, p2, color=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)
```

(Changed in v1.18.4)

PDF only: Draw a line from `p1` to `p2` (`point_like` s). See `Shape.draw_line()`.

```python
draw_zigzag(p1, p2, breadth=2, color=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)
```

(Changed in v1.18.4)

PDF only: Draw a zigzag line from `p1` to `p2` (`point_like` s). See `Shape.draw_zigzag()`.

```python
draw_squiggle(p1, p2, breadth=2, color=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)
```

(Changed in v1.18.4)

PDF only: Draw a squiggly (wavy, undulated) line from `p1` to `p2` (`point_like` s). See `Shape.draw_squiggle()`.

```python
draw_circle(center, radius, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)
```

(Changed in v1.18.4)

PDF only: Draw a circle around `center` (`point_like`) with a radius of `radius`. See `Shape.draw_circle()`.

```python
draw_oval(quad, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)
```

(Changed in v1.18.4)

PDF only: Draw an oval (ellipse) within the given `rect_like` or `quad_like`. See `Shape.draw_oval()`.

```python
draw_sector(center, point, angle, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, fullSector=True, overlay=True, closePath=False, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)
```

(Changed in v1.18.4)
PDF only: Draw a circular sector, optionally connecting the arc to the circle’s center (like a piece of pie). See :meth:`Shape.draw_sector()`.

.. code-block:: python

    def draw_polyline(points, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, closePath=False, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)

(Created in v1.18.4)

PDF only: Draw several connected lines defined by a sequence of point_like s. See :meth:`Shape.draw_polyline()`.

.. code-block:: python

    def draw_bezier(p1, p2, p3, p4, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, closePath=False, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)

(Created in v1.18.4)

PDF only: Draw a cubic Bézier curve from $p_1$ to $p_4$ with the control points $p_2$ and $p_3$ (all are point_likes). See :meth:`Shape.draw_bezier()`.

.. code-block:: python

    def draw_curve(p1, p2, p3, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, closePath=False, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)

(Created in v1.18.4)

PDF only: This is a special case of :meth:`draw_bezier()`. See :meth:`Shape.draw_curve()`.

.. code-block:: python

    def draw_rect(rect, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)

(Created in v1.18.4)

PDF only: Draw a rectangle. See :meth:`Shape.draw_rect()`.

**Note:** An efficient way to background-color a PDF page with the old Python paper color is

```python
>>> col = fitz.utils.getColor("py_color")
>>> page.draw_rect(page.rect, color=col, fill=col, overlay=False)
```

.. code-block:: python

    def draw_quad(quad, color=None, fill=None, width=1, dashes=None, lineCap=0, lineJoin=0, overlay=True, closePath=False, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)

(Created in v1.18.4)

PDF only: Draw a quadrilateral. See :meth:`Shape.draw_quad()`.

.. code-block:: python

    def insert_font(fontname="helv", fontfile=None, fontbuffer=None, set_simple=False, encoding=TEXT_ENCODING_LATIN)

PDF only: Add a new font to be used by text output methods and return its xref. If not already present in the file, the font definition will be added. Supported are the built-in Base14_Fonts and the CJK fonts via “reserved” fontnames. Fonts can also be provided as a file path or a memory area containing the image of a font file.

**Parameters**

- **fontname** *(str)* – The name by which this font shall be referenced when outputting text on this page. In general, you have a “free” choice here (but consult the *Adobe PDF References*, page 56, section 3.2.4 for a formal description of building legal PDF names). However, if it matches one of the Base14_Fonts or one of the CJK fonts, fontfile and fontbuffer are ignored.

In other words, you cannot insert a font via fontfile / fontbuffer and also give it a reserved fontname.

**Note:** A reserved fontname can be specified in any mixture of upper or lower case and still match the right built-in font definition: fontnames “helv”, “Helv”, “HELV”, “Helvetica”, etc. all lead to the same
font definition “Helvetica”. But from a Page perspective, these are different references. You can exploit this fact when using different encoding variants (Latin, Greek, Cyrillic) of the same font on a page.

Parameters

- **fontfile** *(str)* – a path to a font file. If used, *fontname* must be different from all reserved names.

- **fontbuffer** *(bytes/bytearray)* – the memory image of a font file. If used, *fontname* must be different from all reserved names. This parameter would typically be used to transfer fonts between different pages of the same or different PDFs.

- **set_simple** *(int)* – applicable for *fontfile* / *fontbuffer* cases only: enforce treatment as a “simple” font, i.e. one that only uses character codes up to 255.

- **encoding** *(int)* – applicable for the “Helvetica”, “Courier” and “Times” sets of *Base14_Fonts* only. Select one of the available encodings Latin (0), Cyrillic (2) or Greek (1). Only use the default (0 = Latin) for “Symbol” and “ZapfDingBats”.

**Rtype** int

**Returns** the xref of the installed font.

**Note:** Built-in fonts will not lead to the inclusion of a font file. So the resulting PDF file will remain small. However, your PDF viewer software is responsible for generating an appropriate appearance – and there exist differences on whether or how each one of them does this. This is especially true for the CJK fonts. But also Symbol and ZapfDingbats are incorrectly handled in some cases. Following are the Font Names and their correspondingly installed Base Font names:

**Base-14 Fonts**

<table>
<thead>
<tr>
<th>Font Name</th>
<th>Installed Base Font</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>helv</td>

</tbody>
</table>

**CJK Fonts** *(China, Japan, Korea)*

1. If your existing code already uses the installed base name as a font reference (as it was supported by PyMuPDF versions earlier than 1.14), this will continue to work.

2. Not all PDF reader software (including internet browsers and office software) display all of these fonts. And if they do, the difference between the serifed and the non-serifed version may hardly be noticeable. But serifed and non-serifed versions lead to different installed base fonts, thus providing an option to be displayable with your specific PDF viewer.

3. Not all PDF readers display these fonts at all. Some others do, but use a wrong character spacing, etc.

**insert_image**

```
(rect, filename=None, pixmap=None, stream=None, mask=None, rotate=0, oc=None, keep_proportion=True, overlay=True)
```

PDF only: Put an image inside the given rectangle. The image can be taken from a pixmap, a file or a memory area - of these parameters exactly one must be specified.

Changed in version 1.14.11 By default, the image keeps its aspect ratio.

**Parameters**

- **rect (rect_like)** – where to put the image. Must be finite and not empty.
  
  *(Changed in v1.17.6)* No longer needs to have a non-empty intersection with the page’s `Page.cropbox`⁵.

  *(Changed in version 1.14.13)* The image is now always placed centered in the rectangle, i.e. the centers of image and rectangle are equal.

- **filename (str)** – name of an image file (all formats supported by MuPDF – see **Supported Input Image Formats**). If the same image is to be inserted multiple times, choose one of the other two options to avoid some overhead.

- **stream (bytes, bytearray, io.BytesIO)** – image in memory (all formats supported by MuPDF – see **Supported Input Image Formats**). This is the most efficient option.

  Changed in version 1.14.13: `io.BytesIO` is now also supported.

- **pixmap (Pixmap)** – a pixmap containing the image.

- **mask (bytes, bytearray, io.BytesIO)** – *(new in version v1.18.1)* image in memory – to be used as image mask for the base image. When specified, the base image must also be provided as an in-memory image (`stream` parameter).

- **rotate (int)** – *(new in version v1.14.11)* rotate the image. Must be an integer multiple of 90 degrees. If you need a rotation by an arbitrary angle, consider converting the image to a PDF (`Document.convert_to_pdf()`) first and then use `Page.show_pdf_page()` instead.

- **oc (int)** – *(new in v1.18.3)* (`xref`) make image visibility dependent on this OCG (optional content group). Please be aware, that this property is stored with the generated PDF image definition. If you insert the same image anywhere else, but with a different ‘oc’ value, a full additional image copy will be stored.

- **keep_proportion (bool)** – *(new in version v1.14.11)* maintain the aspect ratio of the image.

---

⁵ The previous algorithm caused images to be **shrunk** to this intersection. Now the image can be anywhere on `Page.medibox`, potentially being invisible or only partially visible if the cropbox (representing the visible page part) is smaller.
For a description of overlay see Common Parameters.

This example puts the same image on every page of a document:

```python
>>> doc = fitz.open(...)  
>>> rect = fitz.Rect(0, 0, 50, 50)  # put thumbnail in upper left corner  
>>> img = open("some.jpg", "rb").read()  # an image file  
>>> for page in doc:  
...    page.insert_image(rect, stream = img)  
>>> doc.save(...)  
```

Note:

1. If that same image had already been present in the PDF, then only a reference to it will be inserted. This of course considerably saves disk space and processing time. But to detect this fact, existing PDF images need to be compared with the new one. This is achieved by storing an MD5 code for each image in a table and only compare the new image’s MD5 code against the table entries. Generating this MD5 table, however, is done when the first image is inserted - which therefore may have an extended response time.

2. You can use this method to provide a background or foreground image for the page, like a copyright, a watermark. Please remember, that watermarks require a transparent image . . .

3. The image may be inserted uncompressed, e.g. if a Pixmap is used or if the image has an alpha channel. Therefore, consider using deflate=True when saving the file.

4. The image is stored in the PDF in its original quality. This may be much better than you ever need for your display. In this case consider decreasing the image size before inserting it – e.g. by using the pixmap option and then shrinking it or scaling it down (see Pixmap chapter). The PIL method Image.thumbnail() can also be used for that purpose. The file size savings can be very significant.

5. The most efficient way to display the same image on multiple pages is another method: `show_pdf_page()`. Consult Document.convert_to_pdf() for how to obtain intermediate PDFs usable for that method. Demo script fitz-logo.py implements a fairly complete approach.

`get_text(opt="text", clip=None, flags=None)`

Retrieves the content of a page in a variety of formats. This is a wrapper for TextPage methods by choosing the output option as follows:

- “text” – TextPage.extractTEXT(), default
- “blocks” – TextPage.extractBLOCKS()
- “words” – TextPage.extractWORDS()
- “html” – TextPage.extractHTML()
- “xhtml” – TextPage.extractXHTML()
- “xml” – TextPage.extractXML()
- “dict” – TextPage.extractDICT()
- “json” – TextPage.extractJSON()
- “rawdict” – TextPage.extractRAWDICT()
- “rawjson” – TextPage.extractRAWJSON()
**opt** *(str)* – A string indicating the requested format, one of the above. A mixture of upper and lower case is supported.

Changed in version 1.16.3 Values “words” and “blocks” are now also accepted.

**clip** *(rect-like)* – *(new in v1.17.7)* restrict extracted text to this rectangle. If None, the full page is taken. Has **no effect** for options “html”, “xhtml” and “xml”.

**flags** *(int)* – *(new in version 1.16.2)* indicator bits to control whether to include images or how text should be handled with respect to white spaces and ligatures. See `Preserve Text Flags` for available indicators and `Text Extraction Flags Defaults` for default settings.

**Return type** *str, list, dict*

**Returns** The page’s content as a string, a list or a dictionary. Refer to the corresponding `TextPage` method for details.

---

**Note:**

1. You can use this method as a **document conversion tool** from any supported document type (not only PDF) to one of TEXT, HTML, XHTML or XML documents.

2. The inclusion of text via the **clip** parameter is decided on a by-character level: *(changed in v1.18.2)* a character becomes part of the output, if its bbox is contained in **clip**. This **deviates** from the algorithm used in redaction annotations: a character will be removed if its bbox intersects with some redaction annotation.

---

**get_textbox** *(rect)* *(New in v1.17.7)*

Retrieve the text contained in a rectangle.

**Parameters**

rect *(rect-like)* – rect-like.

**Returns**

a string with interspersed linebreaks where necessary. This is the same as `page.get_text("text", clip=rect, flags=0)` with one removed final line break. A typical use is checking the result of `Page.search_for()`:

```python
>>> rl = page.search_for("currency:")
>>> page.get_textbox(rl[0])
'Currency:'
>>>```

**get_textpage** *(clip=None, flags=3)* *(New in version 1.16.5)*

Create a `TextPage` for the page. This method avoids using an intermediate `DisplayList`.

**Parameters**

- **flags** *(in)* – indicator bits controlling the content available for subsequent extraction – see the parameter of `Page.get_text()`.

- **clip** *(rect-like)* – *(new in v1.17.7)* restrict extracted text to this area – to be used by text extraction methods.

**Returns** `TextPage`
get_drawings()
(New in v1.18.0)

Return the draw commands of the page. These are instructions which draw lines, rectangles or curves, including properties like colors, transparency, line width and dashing, etc.

**Returns** a list of dictionaries. Each dictionary item contains one or more single draw commands which belong together: their lines are connected and they have the same properties (colors, dashing, etc.). This is called a “path” in the PDF specification, but the method works the same for all document types.

The path dictionary has been designed to be compatible with the methods and terminology of class `Shape`. There are the following keys:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>closePath</td>
<td>Same as the parameter in <code>Shape</code>.</td>
</tr>
<tr>
<td>color</td>
<td>Same as the parameter in <code>Shape</code>.</td>
</tr>
<tr>
<td>dashes</td>
<td>Same as the parameter in <code>Shape</code>.</td>
</tr>
<tr>
<td>even_odd</td>
<td>Same as the parameter in <code>Shape</code>.</td>
</tr>
<tr>
<td>fill</td>
<td>Same as the parameter in <code>Shape</code>.</td>
</tr>
<tr>
<td>items</td>
<td>List of draw commands: lines, rectangle or curves.</td>
</tr>
<tr>
<td>lineCap</td>
<td>Number 3-tuple, use its max value on output with <code>Shape</code>.</td>
</tr>
<tr>
<td>lineJoin</td>
<td>Same as the parameter in <code>Shape</code>.</td>
</tr>
<tr>
<td>opacity</td>
<td>represents <code>fill_opacity</code> and <code>stroke_opacity</code> in <code>Shape</code>.</td>
</tr>
<tr>
<td>rect</td>
<td>Page area covered by this path. Information only.</td>
</tr>
<tr>
<td>width</td>
<td>Same as the parameter in <code>Shape</code>.</td>
</tr>
</tbody>
</table>

Each entry in `path["items"]` is one of the following:

- `("l", p1, p2)` - a line from `p1` to `p2` (`Point` objects).
- `("c", p1, p2, p3, p4)` - cubic Bézier curve from `p1` to `p4`, `p2` and `p3` are the control points. All objects are of type `Point`.
- `("re", rect)` - a `Rect`.

Using class `Shape`, you should be able to recreate the original drawings on a separate (PDF) page with high fidelity. A coding draft can be found in section “Extractings Drawings” of chapter *Collection of Recipes*.

The following limitations exist by design:

- The visual appearance of a page may have been designed in a very complex way. For example in PDF, layers (Optional Content Groups) can control the visibility of any item (drawings and other objects) depending on whatever condition: a watermark may be suppressed if the page is shown by a viewer, but is visible if printed on paper.
- Only drawings are extracted, other page content is ignored. The method therefore does not detect whether a drawing is covered, hidden or overlaid in the original document, e.g. by some text or an image.

Effects like these are ignored by the method – it will return all paths unconditionally.

get_fonts (full=False)
PDF only: Return a list of fonts referenced by the page. Wrapper for `Document`. `get_page_fonts()`.

get_images (full=False)
PDF only: Return a list of images referenced by the page. Wrapper for `Document`. `get_page_images()`.
**get_image_bbox**(*item*)

PDF only: Return the boundary box of an image.

*Changed in version 1.17.0:*

- The method should deliver correct results now.
- The page’s /Contents are no longer modified by this method.

**Parameters**

- **item** (*list, str*) – an item of the list `Page.get_images()` with `full=True` specified, or the name entry of such an item, which is item[-3] (or item[7] respectively).

**Return type** `Rect`

**Returns** the boundary box of the image. *(Changed in v1.16.7) – If the page in fact does not display this image, an infinite rectangle is returned now. In previous versions, an exception was raised. (Changed in v1.17.0) – Only images referenced directly by the page are considered. This means that images occurring in embedded PDF pages are ignored and an exception is raised. (Changed in v1.18.5) – Removed the restriction introduced in v1.17.0. The base MuPDF library now more reliably computes that value.*

---

**Note:**

- Be aware that `Page.get_images()` may contain “dead” entries, i.e. images **not displayed** by this page (some PDFs contain a central list of all images, to save specification effort on the page level). In this case an infinite rectangle is returned.

**get_svg_image**(*matrix=fitz.Identity, text_as_path=True*)

Create an SVG image from the page. Only full page images are currently supported.

**Parameters**

- **matrix** (*matrix_like*) – a matrix, default is `Identity`.
- **text_as_path** (*bool*) – *(new in v1.17.5) – controls how text is represented. True outputs each character as a series of elementary draw commands, which leads to a more precise text display in browsers, but a very much larger output for text-oriented pages. Display quality for False relies on the presence of the referenced fonts on the current system. For missing fonts, the internet browser will fall back to some default – leading to unpleasant appearances. Choose False if you want to parse the text of the SVG.*

**Returns** a UTF-8 encoded string that contains the image. Because SVG has XML syntax it can be saved in a text file with extension `.svg`.

**get_pixmap**(*matrix=fitz.Identity, colorspace=fitz.csRGB, clip=None, alpha=False, annots=True*)

Create a pixmap from the page. This is probably the most often used method to create a Pixmap.

**Parameters**

- **matrix** (**matrix_like**) – default is `Identity`.
- **colorspace** (*str or Colorspace*) – Defines the required colorspace, one of “GRAY”, “RGB” or “CMYK” (case insensitive). Or specify a `Colorspace`, ie. one of the predefined ones: `csGRAY`, `csRGB` or `csCMYK`.
- **clip** (*irect_like*) – restrict rendering to this area.
• **alpha** *(bool)* – whether to add an alpha channel. Always accept the default *False* if you do not really need transparency. This will save a lot of memory (25% in case of RGB … and pixmaps are typically large!), and also processing time. Also note an important difference in how the image will be rendered: with *True* the pixmap’s samples area will be pre-cleared with 0x00. This results in transparent areas where the page is empty. With *False* the pixmap’s samples will be pre-cleared with 0xff. This results in white where the page has nothing to show.

**Changed in version 1.14.17** The default alpha value is now *False*.

– Generated with *alpha=True*

– Generated with *alpha=False*

• **annots** *(bool)* – *(new in version 1.16.0)* whether to also render annotations or to suppress them. You can create pixmaps for annotations separately.

**Return type** **Pixmap**

**Returns** Pixmap of the page. For fine-controlling the generated image, the by far most important parameter is **matrix**. E.g. you can increase or decrease the image resolution by using **Matrix(xzoom, yzoom)**. If zoom > 1, you will get a higher resolution: zoom=2 will double the number of pixels in that direction and thus generate a 2 times larger image. Non-positive values will flip horizontally, resp. vertically. Similarly, matrices also let you rotate or shear, and you can combine effects via e.g. matrix multiplication. See the **Matrix** section to learn more.

**annot_names()**

*(New in version 1.16.10)*

PDF only: return a list of the names of annotations, widgets and links. Technically, these are the /NM values of every PDF object found in the page’s /Annots array.

**Return type** list
annot_xrefs()  
(New in version 1.17.1)  
PDF only: return a list of the `data`'xref` numbers of annotations, widgets and links – technically of all entries found in the page’s /Annots array.

**Return type**  list

**Returns**  a list of items (xref, type) where type is the annotation type. Use the type to tell apart links, fields and annotations, see Annotation Types.

load_annot( ident)  
(New in version 1.17.1)  
PDF only: return the annotation identified by `ident`. This may be its unique name (PDF /NM key), or its xref.

**Parameters**  ident(str, int) – the annotation name or xref.

**Return type**  Annot

**Returns**  the annotation or None.

**Note:** Methods `Page.annot_names()`, `Page.annots_xrefs()` provide lists of names or xrefs, respectively, from where an item may be picked and loaded via this method.

load_links()  
Return the first link on a page. Synonym of property `firstLink`.

**Return type**  Link

**Returns**  first link on the page (or None).

set_rotation( rotate)  
PDF only: Sets the rotation of the page.

**Parameters**  rotate(int) – An integer specifying the required rotation in degrees. Must be an integer multiple of 90. Values will be converted to one of 0, 90, 180, 270.

show_pdf_page( rect, docsrc, pno=0, keep_proportion=True, overlay=True, oc=0, rotate=0, clip=None)  
PDF only: Display a page of another PDF as a vector image (otherwise similar to `Page.insert_image()`). This is a multi-purpose method. For example, you can use it to

- create “n-up” versions of existing PDF files, combining several input pages into one output page (see example 4-up.py),
- create “posterized” PDF files, i.e. every input page is split up in parts which each create a separate output page (see posterize.py),
- include PDF-based vector images like company logos, watermarks, etc., see svg-logo.py, which puts an SVG-based logo on each page (requires additional packages to deal with SVG-to-PDF conversions).

**Changed in version 1.14.11**  Parameter `reuse_xref` has been deprecated.

**Parameters**

- rect(rect_like) – where to place the image on current page. Must be finite and its intersection with the page must not be empty.

**Changed in version 1.14.11**  Position the source rectangle centered in this rectangle.
• **docs** *(Document)* – source PDF document containing the page. Must be a different document object, but may be the same file.

• **pno**(int) – page number (0-based, in \(-\infty < \text{pno} < \text{docs}.\text{page_count}\)) to be shown.

• **keep_proportion**(bool) – whether to maintain the width-height-ratio (default). If false, all 4 corners are always positioned on the border of the target rectangle – whatever the rotation value. In general, this will deliver distorted and/or non-rectangular images.

• **overlay**(bool) – put image in foreground (default) or background.

• **oc**(int) – *(new in v1.18.3)*(xref) make visibility dependent on this OCG (optional content group).

• **rotate**(float) – *(new in version 1.14.10)* show the source rectangle rotated by some angle. *Changed in version 1.14.11:* Any angle is now supported.

• **clip**(rect_like) – choose which part of the source page to show. Default is the full page, else must be finite and its intersection with the source page must not be empty.

**Note:** In contrast to method *Document.insert_pdf()* , this method does not copy annotations or links, so they are not shown. But all its other resources *(text, images, fonts, etc.)* will be imported into the current PDF. They will therefore appear in text extractions and in *get_fonts()* and *get_images()* lists – even if they are not contained in the visible area given by clip.

Example: Show the same source page, rotated by 90 and by -90 degrees:

```python
doc = fitz.open()  # new empty PDF
page=doc.new_page()  # new page in A4 format

# upper half page
r1 = fitz.Rect(0, 0, page.rect.width, page.rect.height/2)

# lower half page
r2 = r1 + (0, page.rect.height/2, 0, page.rect.height/2)

src = fitz.open("PyMuPDF.pdf")  # show page 0 of this

page.show_pdf_page(r1, src, 0, rotate=90)
page.show_pdf_page(r2, src, 0, rotate=-90)
doc.save("show.pdf")```

6.12. Page 179
new_shape()

PDF only: Create a new Shape object for the page.

**Return type** Shape

**Returns** a new Shape to use for compound drawings. See description there.

search_for (needle, clip=clip, quads=False, flags=TEXT_DEHYPHENATE)

*(Changed in v1.18.2)*

Search for needle on a page. Wrapper for TextPage.search().

**Parameters**

- **needle** *(str)* – Text to search for. Upper / lower case is ignored. May contain spaces.
- **clip** *(rect_like)* *(New in v1.18.2)* only search within this area.
- **quads** *(bool)* – Return object type Quad instead of Rect.
- **flags** *(int)* – Control the data extracted by the underlying TextPage. By default ligatures are expanded, white space is replaced with spaces and hyphenation is detected.

**Return type** list

**Returns**

A list of Rect or Quad objects, each of which – normally! – surrounds one occurrence of needle. **However:** if parts of needle occur on more than one line, then a separate item is generated for each these parts. So, if needle = "search string", two rectangles may be generated.

**Changes in v1.18.2:**
• There no longer is a limit on the list length (removal of the `hit_max` parameter).

• If a word is **hyphenated** at a line break, it will still be found. E.g. the word “method” will be found even if hyphenated as “meth-od” by a line break, and two rectangles will be returned: one surrounding “meth” (without the hyphen) and another one surrounding “od”.

**Note:** The method supports multi-line text marker annotations: you can use the full returned list as **one single** parameter for creating the annotation.

**Caution:**

- There is a tricky aspect: the search logic regards **contiguous multiple occurrences of needle** as one: assuming `needle` is “abc”, and the page contains “abc” and “abcabc”, then only **two** rectangles will be returned, one for “abc”, and a second one for “abcabc”.

- You can always use `Page.get_textbox()` to check what text actually is being surrounded by each rectangle.

```python
set_mediabox(r)
```

PDF only: *(New in v1.16.13)* Change the physical page dimension by setting `mediabox` in the page’s object definition.

**Parameters** `r (rect-like)` – the new `mediabox` value.

**Note:** This method also sets the page’s `cropbox` to the same value – to prevent mismatches caused by values further up in the parent hierarchy.

**Caution:** For non-empty pages this may have undesired effects, because content depends on this value and will change position or even disappear.

```python
set_cropbox(r)
```

PDF only: change the visible part of the page.

**Parameters** `r (rect_like)` – the new visible area of the page. Note that this **must** be specified in **unrotated coordinates**.

After execution if the page is not rotated, `Page.rect` will equal this rectangle, but shifted to the top-left position (0, 0) if necessary. Example session:

```python
>>> page = doc.new_page()
>>> page.rect
fitz.Rect(0.0, 0.0, 595.0, 842.0)

>>> page.crobbox
fitz.Rect(0.0, 0.0, 595.0, 842.0)

# now set cropbox to a part of the page
>>> page.setcropbox(fitz.Rect(100, 100, 400, 400))

# this will also change the "rect" property:
>>> page.rect
fitz.Rect(0.0, 0.0, 300.0, 300.0)
```
>>> # but mediabox remains unaffected
>>> page.mediabox
fitz.Rect(0.0, 0.0, 595.0, 842.0)

>>> # revert everything we did
>>> page.setcropbox(page.mediabox)
>>> page.rect
fitz.Rect(0.0, 0.0, 595.0, 842.0)

rotation
Contains the rotation of the page in degrees (always 0 for non-PDF types).

    Type  int

cropbox_position
Contains the top-left point of the page’s /cropbox for a PDF, otherwise Point(0, 0).

    Type  Point

cropbox
The page’s /cropbox for a PDF. Always the unrotated page rectangle is returned. For a non-PDF this will always equal the page rectangle.

    Type  Rect

mediabox_size
Contains the width and height of the page’s Page.mediabox for a PDF, otherwise the bottom-right coordinates of Page.rect.

    Type  Point

mediabox
The page’s mediabox for a PDF, otherwise Page.rect.

    Type  Rect

Note:  For most PDF documents and for all other document types, page.rect == page.cropbox == page.mediabox is true. However, for some PDFs the visible page is a true subset of mediabox. Also, if the page is rotated, its Page.rect may not equal Page.cropbox. In these cases the above attributes help to correctly locate page elements.

transformation_matrix
This matrix translates coordinates from the PDF space to the MuPDF space. For example, in PDF / Rect [x0 y0 x1 y1] the pair (x0, y0) specifies the bottom-left point of the rectangle – in contrast to MuPDF’s system, where (x0, y0) specify top-left. Multiplying the PDF coordinates with this matrix will deliver the (Py-) MuPDF rectangle version. Obviously, the inverse matrix will again yield the PDF rectangle.

    Type  Matrix

rotation_matrix

derotation_matrix
These matrices may be used for dealing with rotated PDF pages. When adding / inserting anything to a PDF page, the coordinates of the unrotated page are always used. These matrices help translating between the two states. Example: if a page is rotated by 90 degrees – what would then be the coordinates of the top-left Point(0, 0) of an A4 page?
>>> page.set_rotation(90)  # rotate an ISO A4 page
>>> page.rect
Rect(0.0, 0.0, 842.0, 595.0)
>>> p = fitz.Point(0, 0)  # where did top-left point land?
>>> p * page.rotation_matrix
Point(842.0, 0.0)

Type \textit{Matrix}

\textbf{first\_link}
Contains the first \textit{Link} of a page (or \textit{None}).

Type \textit{Link}

\textbf{first\_annot}
Contains the first \textit{Annot} of a page (or \textit{None}).

Type \textit{Annot}

\textbf{first\_widget}
Contains the first \textit{Widget} of a page (or \textit{None}).

Type \textit{Widget}

\textbf{number}
The page number.

Type \textit{int}

\textbf{parent}
The owning document object.

Type \textit{Document}

\textbf{rect}
Contains the rectangle of the page. Same as result of \textit{Page.bound()}.

Type \textit{Rect}

\textbf{xref}
The page’s PDF \textit{xref}. Zero if not a PDF.

Type \textit{Rect}

\subsection{6.12.2 Description of \textit{get\_links()} Entries}

Each entry of the \textit{Page.get\_links()} list is a dictionary with the following keys:

- \textit{kind}: (required) an integer indicating the kind of link. This is one of \textit{LINK\_NONE}, \textit{LINK\_GOTO}, \textit{LINK\_GOTOR}, \textit{LINK\_LAUNCH}, or \textit{LINK\_URI}. For values and meaning of these names refer to \textit{Link Destination Kinds}.

- \textit{from}: (required) a \textit{Rect} describing the “hot spot” location on the page’s visible representation (where the cursor changes to a hand image, usually).

- \textit{page}: a 0-based integer indicating the destination page. Required for \textit{LINK\_GOTO} and \textit{LINK\_GOTOR}, else ignored.
• \textit{to}: either a \texttt{fitz.Point}, specifying the destination location on the provided page, default is \texttt{fitz.Point(0, 0)}, or a symbolic (indirect) name. If an indirect name is specified, \textit{page} = \texttt{-1} is required and the name must be defined in the PDF in order for this to work. Required for \texttt{LINK_GOTO} and \texttt{LINK_GOTOR}, else ignored.

• \textit{file}: a string specifying the destination file. Required for \texttt{LINK_GOTOR} and \texttt{LINK_LAUNCH}, else ignored.

• \textit{uri}: a string specifying the destination internet resource. Required for \texttt{LINK_URI}, else ignored.

• \textit{xref}: an integer specifying the PDF \texttt{xref} of the link object. Do not change this entry in any way. Required for link deletion and update, otherwise ignored. For non-PDF documents, this entry contains \texttt{-1}. It is also \texttt{-1} for all entries in the \texttt{get_links()} list, if any of the links is not supported by MuPDF - see the note below.

6.12.3 Notes on Supporting Links

MuPDF’s support for links has changed in \texttt{v1.10a}. These changes affect link types \texttt{LINK_GOTO} and \texttt{LINK_GOTOR}.

6.12.3.1 Reading (pertains to method \texttt{get_links()} and the \texttt{firstLink} property chain)

If MuPDF detects a link to another file, it will supply either a \texttt{LINK_GOTOR} or a \texttt{LINK_LAUNCH} link kind. In case of \texttt{LINK_GOTOR} destination details may either be given as page number (eventually including position information), or as an indirect destination.

If an indirect destination is given, then this is indicated by \texttt{page} = \texttt{-1}, and \texttt{link.dest.dest} will contain this name. The dictionaries in the \texttt{get_links()} list will contain this information as the \texttt{to} value.

Internal links are always of kind \texttt{LINK_GOTO}. If an internal link specifies an indirect destination, it will always be resolved and the resulting direct destination will be returned. Names are never returned for internal links, and undefined destinations will cause the link to be ignored.

6.12.3.2 Writing

PyMuPDF writes (updates, inserts) links by constructing and writing the appropriate PDF object \texttt{source}. This makes it possible to specify indirect destinations for \texttt{LINK_GOTOR} and \texttt{LINK_GOTO} link kinds (pre PDF 1.2 file formats are not supported).

\textbf{Warning:} If a \texttt{LINK_GOTO} indirect destination specifies an undefined name, this link can later on not be found / read again with MuPDF / PyMuPDF. Other readers however will detect it, but flag it as erroneous.

Indirect \texttt{LINK_GOTOR} destinations can in general of course not be checked for validity and are therefore always accepted.

6.12.4 Homologous Methods of Document and Page

This is an overview of homologous methods on the \texttt{Document} and on the \texttt{Page} level.

<table>
<thead>
<tr>
<th>Document Level</th>
<th>Page Level</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{Document.get_page_fonts(pno)}</td>
<td>\texttt{Page.get_fonts() }</td>
</tr>
<tr>
<td>\texttt{Document.get_page_images(pno)}</td>
<td>\texttt{Page.get_images() }</td>
</tr>
<tr>
<td>\texttt{Document.get_page_pixmap(pno, . . . )}</td>
<td>\texttt{Page.get_pixmap()}</td>
</tr>
<tr>
<td>\texttt{Document.get_page_text(pno, . . . )}</td>
<td>\texttt{Page.get_text() }</td>
</tr>
<tr>
<td>\texttt{Document.search_page_for(pno, . . . )}</td>
<td>\texttt{Page.search_for() }</td>
</tr>
</tbody>
</table>
The page number “pno” is a 0-based integer \(-\infty < \text{pno} < \text{page}\_\text{count}\).

Note: Most document methods (left column) exist for convenience reasons, and are just wrappers for: Document[pno].<page method>. So they load and discard the page on each execution.

However, the first two methods work differently. They only need a page’s object definition statement - the page itself will not be loaded. So e.g. Page.get_fonts() is a wrapper the other way round and defined as follows: page.get_fonts == page.parent.get_page_fonts(page.number).

6.13 Pixmap

Pixmaps (“pixel maps”) are objects at the heart of MuPDF’s rendering capabilities. They represent plane rectangular sets of pixels. Each pixel is described by a number of bytes (“components”) defining its color, plus an optional alpha byte defining its transparency.

In PyMuPDF, there exist several ways to create a pixmap. Except the first one, all of them are available as overloaded constructors. A pixmap can be created ... 

1. from a document page (method Page.get pixmap())
2. empty, based on Colorspace and IRect information
3. from a file
4. from an in-memory image
5. from a memory area of plain pixels
6. from an image inside a PDF document
7. as a copy of another pixmap

Note: A number of image formats is supported as input for points 3. and 4. above. See section Supported Input Image Formats.

Have a look at the Collection of Recipes section to see some pixmap usage “at work”.

<table>

</table>

Class API

```python
class Pixmap

__init__(self, colorspace, irect, alpha)

New empty pixmap: Create an empty pixmap of size and origin given by the rectangle. So, irect.top_left designates the top left corner of the pixmap, and its width and height are irect.width resp. irect.height. Note that the image area is not initialized and will contain crap data – use eg. clearWith() or setRect() to be sure.

Parameters

• colorspace (Colorspace) – colorspace.

• irect (irect_like) – Tte pixmap’s position and dimension.

• alpha (bool) – Specifies whether transparency bytes should be included. Default is False.

__init__(self, colorspace, source)

Copy and set colorspace: Copy source pixmap converting colorspace. Any colorspace combination is possible, but source colorspace must not be None.

Parameters

• colorspace (Colorspace) – desired target colorspace. This may also be None. In this case, a “masking” pixmap is created: its Pixmap.samples will consist of the source’s alpha bytes only.

• source (Pixmap) – the source pixmap.

__init__(self, source, width, height[, clip])

Copy and scale: Copy source pixmap, scaling new width and height values – the image will appear stretched or shrunk accordingly. Supports partial copying. The source colorspace may be None.

Parameters

• source (Pixmap) – the source pixmap.
• **width** (*float*) – desired target width.
• **height** (*float*) – desired target height.
• **clip** (*irect_like*) – restrict the resulting pixmap to this region of the scaled pixmap.

**Note:** If width or height are not *de facto* integers (i.e. \texttt{float(int(value)) != value}), then the resulting pixmap will have an alpha channel.

---

```
__init__(self, source, alpha=1)
```

**Copy and add or drop alpha:** Copy `source` and add or drop its alpha channel. Identical copy if `alpha` equals `source.alpha`. If an alpha channel is added, its values will be set to 255.

**Parameters**

• **source** (*Pixmap*) – source pixmap.

• **alpha** (*bool*) – whether the target will have an alpha channel, default and mandatory if source colorspace is `None`.

**Note:** A typical use includes separation of color and transparency bytes in separate pixmaps. Some applications require this like e.g. \texttt{wx.Bitmap.FromBufferAndAlpha()} of \texttt{wxPython}:

```python
>>> # 'pix' is an RGBA pixmap
>>> pixcolors = fitz.Pixmap(pix, 0)  # extract the RGB part (drop alpha)
>>> pixalpha = fitz.Pixmap(None, pix)  # extract the alpha part
>>> bm = wx.Bitmap.FromBufferAndAlpha(pix.width, pix.height, pixcolors.samples, pixalpha.samples)
```

---

```
__init__(self, filename)
```

**From a file:** Create a pixmap from `filename`. All properties are inferred from the input. The origin of the resulting pixmap is \((0, 0)\).

**Parameters**

**filename** (*str*) – Path of the image file.

```
__init__(self, filename)
```

**From memory:** Create a pixmap from a memory area. All properties are inferred from the input. The origin of the resulting pixmap is \((0, 0)\).

**Parameters**

• **stream** (*bytes, bytearray, BytesIO*) – Data containing a complete, valid image. Could have been created by e.g. \texttt{stream = bytearray(open('image.file', 'rb').read())}. Type `bytes` is supported in \texttt{Python 3 only}, because `bytes == str` in Python 2 and the method will interpret the stream as a filename.

*Changed in version 1.14.13:* \texttt{io.BytesIO} is now also supported.

```
__init__(self, colorspace, width, height, samples, alpha)
```

**From plain pixels:** Create a pixmap from `samples`. Each pixel must be represented by a number of bytes as controlled by the `colorspace` and `alpha` parameters. The origin of the resulting pixmap is \((0, 0)\). This method is useful when raw image data are provided by some other program – see Collection of Recipes.

**Parameters**

• **colorspace** (*Colorspace*) – Colorspace of image.

• **width** (*int*) – image width

• **height** (*int*) – image height

---

6.13. Pixmap 187
• **samples** (*bytes*, *bytearray*, *BytesIO*) – an area containing all pixels of the image. Must include alpha values if specified.

  *Changed in version 1.14.13:* (1) *io.BytesIO* can now also be used. (2) Data are now copied to the pixmap, so may safely be deleted or become unavailable.

• **alpha** (*bool*) – whether a transparency channel is included.

**Note:**

1. The following equation must be true: \((\text{colorspace.n} + \alpha) \times \text{width} \times \text{height} = \text{len(samples)}\).

2. Starting with version 1.14.13, the samples data are copied to the pixmap.

```python
__init__(self, doc, xref)
```

**From a PDF image:** Create a pixmap from an image contained in PDF *doc* identified by its *xref*. All pixmap properties are set by the image. Have a look at `extract-img1.py` and `extract-img2.py` to see how this can be used to recover all of a PDF’s images.

**Parameters**

- **doc** (*Document*) – an opened PDF document.

- **xref** (*int*) – the *xref* of an image object. For example, you can make a list of images used on a particular page with `Document.get_page_images()`, which also shows the *xref* numbers of each image.

```python
clearWith([value, irect])
```

Initialize the samples area.

**Parameters**

- **value** (*int*) – if specified, values from 0 to 255 are valid. Each color byte of each pixel will be set to this value, while alpha will be set to 255 (non-transparent) if present. If omitted, then all bytes (including any alpha) are cleared to 0x00.

- **irect** (*irect_like*) – the area to be cleared. Omit to clear the whole pixmap. Can only be specified, if *value* is also specified.

```python
tintWith(red, green, blue)
```

Colorize (tint) a pixmap with a color provided as an integer triple (red, green, blue). Only colorspace *CS_GRAY* and *CS_RGB* are supported, others are ignored with a warning.

If the colorspace is *CS_GRAY*, \((\text{red} + \text{green} + \text{blue})/3\) will be taken as the tint value.

**Parameters**

- **red** (*int*) – red component.

- **green** (*int*) – green component.

- **blue** (*int*) – blue component.

```python
gammaWith(gamma)
```

Apply a gamma factor to a pixmap, i.e. lighten or darken it. Pixmaps with colorspace *None* are ignored with a warning.

**Parameters**

- **gamma** (*float*) – \(\gamma = 1.0\) does nothing, \(\gamma < 1.0\) lightens, \(\gamma > 1.0\) darkens the image.

```python
shrink(n)
```

Shrink the pixmap by dividing both, its width and height by \(2^n\).
Parameters **n (int)** – determines the new pixmap (samples) size. For example, a value of 2 divides width and height by 4 and thus results in a size of one 16th of the original. Values less than 1 are ignored with a warning.

**Note:** Use this methods to reduce a pixmap’s size retaining its proportion. The pixmap is changed “in place”. If you want to keep original and also have more granular choices, use the resp. copy constructor above.

**pixel(x, y)**

*New in version: 1.14.5:* Return the value of the pixel at location (x, y) (column, line).

**Parameters**

- **x (int)** – the column number of the pixel. Must be in `range(pix.width)`.
- **y (int)** – the line number of the pixel. Must be in `range(pix.height)`.

**Return type** list

**Returns** a list of color values and, potentially the alpha value. Its length and content depend on the pixmap’s colorspace and the presence of an alpha. For RGBA pixmaps the result would e.g. be `[r, g, b, a]`. All items are integers in `range(256)`.

**setPixel(x, y, color)**

*New in version 1.14.7:* Set the color of the pixel at location (x, y) (column, line).

**Parameters**

- **x (int)** – the column number of the pixel. Must be in `range(pix.width)`.
- **y (int)** – the line number of the pixel. Must be in `range(pix.height)`.
- **color (sequence)** – the desired color given as a sequence of integers in `range(256)`. The length of the sequence must equal `Pixmap.n`, which includes any alpha byte.

**setRect (irect, color)**

*New in version 1.14.8:* Set the pixels of a rectangle to a color.

**Parameters**

- **irect (irect_like)** – the rectangle to be filled with the color. The actual area is the intersection of this parameter and `Pixmap.irect`. For an empty intersection (or an invalid parameter), no change will happen.
- **color (sequence)** – the desired color given as a sequence of integers in `range(256)`. The length of the sequence must equal `Pixmap.n`, which includes any alpha byte.

**Return type** bool

**Returns** False if the rectangle was invalid or had an empty intersection with `Pixmap.irect`, else True.

**Note:**

1. This method is equivalent to `Pixmap.setPixel()` executed for each pixel in the rectangle, but is obviously very much faster if many pixels are involved.
2. This method can be used similar to `Pixmap.clearWith()` to initialize a pixmap with a certain color like this: `pix.setRect(pix.irect, (255, 255, 0))` (RGB example, colors the complete pixmap with yellow).

```
setOrigin(x, y)
(New in v1.17.7) Set the x and y values.

Parameters

- `x (int)` – x coordinate
- `y (int)` – y coordinate
```

```
setResolution(xres, yres)
(New in v1.16.17) Set the resolution (dpi) in x and y direction.

(Changed in v1.18.0) When saving as a PNG image, these values will be stored now.

Parameters

- `xres (int)` – resolution in x direction.
- `yres (int)` – resolution in y direction.
```

```
setAlpha([alphavalues])
Change the alpha values. The pixmap must have an alpha channel.

Parameters `alphavalues (bytes, bytearray, BytesIO)` – the new alpha values. If provided, its length must be at least `width * height`. If omitted, all alpha values are set to 255 (no transparency).

Changed in version 1.14.13: `io.BytesIO` is now also supported.
```

```
invertIRect([irect])
Invert the color of all pixels in `IRect irect`. Will have no effect if colorspace is `None`.

Parameters `irect (irect_like)` – The area to be inverted. Omit to invert everything.
```

```
copyPixmap(source, irect)
Copy the `irect` part of the `source` pixmap into the corresponding area of this one. The two pixmaps may have different dimensions and can each have `CS_GRAY` or `CS_RGB` colorspace, but they currently **must** have the same alpha property\(^2\). The copy mechanism automatically adjusts discrepancies between source and target like so:

If copying from `CS_GRAY` to `CS_RGB`, the source gray-shade value will be put into each of the three rgb component bytes. If the other way round, \((r + g + b) / 3\) will be taken as the gray-shade value of the target.

Between `irect` and the target pixmap’s rectangle, an “intersection” is calculated at first. This takes into account the rectangle coordinates and the current attribute values `source.x` and `source.y` (which you are free to modify for this purpose). Then the corresponding data of this intersection are copied. If the intersection is empty, nothing will happen.

Parameters

- `source (Pixmap)` – source pixmap.
- `irect (irect_like)` – The area to be copied.
```

```
writeImage(filename, output=None)
Save pixmap as an image file. Depending on the output chosen, only some or all colorspace are supported

\(^2\) To also set the alpha property, add an additional step to this method by dropping or adding an alpha channel to the result.
and different file extensions can be chosen. Please see the table below. Since MuPDF v1.10a the \texttt{savealpha} option is no longer supported and will be silently ignored.

\textbf{Parameters}

- \texttt{filename (str)} – The filename to save to. The filename’s extension determines the image format, if not overridden by the output parameter.
- \texttt{output (str)} – The requested image format. The default is the filename’s extension. If not recognized, \texttt{png} is assumed. For other possible values see \textit{Supported Output Image Formats}.

\textbf{writePNG (filename)}

Equal to \texttt{pix.writeImage(filename, \texttt{"png"})}.

\textbf{getImageData (output=\texttt{"png"})}

\textit{New in version 1.14.5}: Return the pixmap as a bytes memory object of the specified format – similar to \texttt{writeImage()}.  

\textbf{Parameters output (str)} – The requested image format. The default is \texttt{“png”} for which this function equals \texttt{getPNGData()}. For other possible values see \textit{Supported Output Image Formats}.

\textbf{Return type} bytes

\textbf{getPNGdata ()}

\textbf{getPNGData ()}

Equal to \texttt{pix.getImageData(\texttt{“png”})}.

\textbf{Return type} bytes

\textbf{pillowWrite (*args, **kwargs)}

\textit{(New in v1.17.3)}

Write the pixmap as an image file using Pillow. Use this method for image formats or extended image features not supported by MuPDF. Examples are

- Formats JPEG, JPX, J2K, WebP, etc.
- Storing EXIF information.
- If you do not provide dpi information, the values \texttt{xres}, \texttt{yres} stored with the pixmap are automatically used.

A simple example: \texttt{pix.pillowWrite(\texttt{“some.jpg”, optimize=True, dpi=(150, 150)})}. For details on other parameters see the Pillow documentation.

\textbf{Note: \textit{(Changed in v1.18.0)}} \texttt{Pixmap.writeImage()} and \texttt{Pixmap.writePNG()} now also set resolution / dpi from \texttt{xres} / \texttt{yres} automatically, when saving a PNG image.

\textbf{pillowData (*args, **kwargs)}

\textit{(New in v1.17.3)}

Return an image as a bytes object in the specified format using Pillow. For example \texttt{stream = pix.pillowData(format=\texttt{“JPEG”}, optimize=True)}. Also see above. For details on other parameters see the Pillow documentation.

\textbf{alpha}

Indicates whether the pixmap contains transparency information.

\textbf{Type} bool
**colorspace**

The colorspace of the pixmap. This value may be *None* if the image is to be treated as a so-called *image mask* or *stencil mask* (currently happens for extracted PDF document images only).

*Type* *Colorspace*

**stride**

Contains the length of one row of image data in *Pixmap.samples*. This is primarily used for calculation purposes. The following expressions are true:

- \( \text{len(samples)} == \text{height} \times \text{stride} \)
- \( \text{width} \times n == \text{stride} \).

*Type* *int*

**irect**

Contains the *IRect* of the pixmap.

*Type* *IRect*

**samples**

The color and (if *Pixmap.alpha* is true) transparency values for all pixels. It is an area of \( \text{width} \times \text{height} \times n \) bytes. Each \( n \) bytes define one pixel. Each successive \( n \) bytes yield another pixel in scanline order. Subsequent scanlines follow each other with no padding. E.g. for an RGBA colorspace this means, *samples* is a sequence of bytes like \( \ldots, R, G, B, A, \ldots \), and the four byte values \( R, G, B, A \) define one pixel.

This area can be passed to other graphics libraries like PIL (Python Imaging Library) to do additional processing like saving the pixmap in other image formats.

**Note:**

- The underlying data is a typically **large** memory area from which a *bytes* copy is made for this attribute: for example an RGB-rendered letter page has a samples size of almost 1.4 MB. So consider assigning a new variable if you repeatedly use it.
- Any changes to the underlying data are available only after again accessing this attribute.

*Type* *bytes*

**size**

Contains \( \text{len(pixmap)} \). This will generally equal \( \text{len(pix.samples)} \) plus some platform-specific value for defining other attributes of the object.

*Type* *int*

**width**

w

Width of the region in pixels.

*Type* *int*

**height**

h

Height of the region in pixels.

*Type* *int*
x
X-coordinate of top-left corner

Type int

y
Y-coordinate of top-left corner

Type int

n
Number of components per pixel. This number depends on colorspace and alpha. If colorspace is not None (stencil masks), then Pixmap.n - Pixmap.alpha == pixmap.colorspace.n is true. If colorspace is None, then n == alpha == 1.

Type int

xres
Horizontal resolution in dpi (dots per inch). Please also see resolution.

Type int

yres
Vertical resolution in dpi. Please also see resolution.

Type int

interpolate
An information-only boolean flag set to True if the image will be drawn using “linear interpolation”. If False “nearest neighbour sampling” will be used.

Type bool

### 6.13.1 Supported Input Image Formats

The following file types are supported as input to construct pixmaps: BMP, JPEG, GIF, TIFF, JXR, JPX, PNG, PAM and all of the Portable Anymap family (PBM, PGM, PNM, PPM). This support is two-fold:

1. Directly create a pixmap with Pixmap(filename) or Pixmap(byterray). The pixmap will then have properties as determined by the image.

2. Open such files with fitz.open(...). The result will then appear as a document containing one single page. Creating a pixmap of this page offers all the options available in this context: apply a matrix, choose colorspace and alpha, confine the pixmap to a clip area, etc.

SVG images are only supported via method 2 above, not directly as pixmaps. But remember: the result of this is a raster image as is always the case with pixmaps¹.

### 6.13.2 Supported Output Image Formats

A number of image output formats are supported. You have the option to either write an image directly to a file (Pixmap.writeImage()), or to generate a bytes object (Pixmap imageData()). Both methods accept a 3-letter string identifying the desired format (Format column below). Please note that not all combinations of pixmap colorspace, transparency support (alpha) and image format are possible.

1 If you need a vector image from the SVG, you must first convert it to a PDF. Try Document.convert_to_pdf(). If this is not good enough, look for other SVG-to-PDF conversion tools like the Python packages svglib, CairoSVG, Uniconvertor or the Java solution Apache Batik. Have a look at our Wiki for more examples.
<table>
<thead>
<tr>
<th>Format</th>
<th>Colorspaces</th>
<th>alpha</th>
<th>Extensions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Adobe Photoshop Document</td>
</tr>
</tbody>
</table>

Note:

- Not all image file types are supported (or at least common) on all OS platforms. E.g. PAM and the Portable Anymap formats are rare or even unknown on Windows.
- Especially pertaining to CMYK colorspaces, you can always convert a CMYK pixmap to an RGB pixmap with `rgb_pix = fitz.Pixmap(fitz.csRGB, cmyk_pix)` and then save that in the desired format.
- As can be seen, MuPDF’s image support range is different for input and output. Among those supported both ways, PNG is probably the most popular. We recommend using Pillow whenever you face a support gap.
- We also recommend using “ppm” formats as input to tkinter’s `PhotoImage` method like this: `tkimg = tkinter.PhotoImage(data=pix.getImageData("ppm"))` (also see the tutorial). This is very fast (60 times faster than PNG) and will work under Python 2 or 3.

### 6.14 Point

Point represents a point in the plane, defined by its x and y coordinates.

<table>
<thead>
<tr>
<th>Attribute / Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Point.distance_to()</td>
<td>calculate distance to point or rect</td>
</tr>
<tr>
<td>Point.norm()</td>

<td>transform point with a matrix</td>
</tr>
<tr>
<td>Point.abs_unit</td>
<td>same as unit, but positive coordinates</td>
</tr>
<tr>
<td>Point.unit</td>
<td>point coordinates divided by abs(point)</td>
</tr>
<tr>
<td>Point.x</td>
<td>the X-coordinate</td>
</tr>
<tr>
<td>Point.y</td>
<td>the Y-coordinate</td>
</tr>
</tbody>
</table>

Class API

class Point

```python
__init__(self)
__init__(self, x, y)
__init__(self, point)
__init__(self, sequence)
```

Overloaded constructors.

Without parameters, `Point(0, 0)` will be created.
With another point specified, a **new copy** will be created, “sequence” is a Python sequence of 2 numbers (see *Using Python Sequences as Arguments in PyMuPDF*).

**Parameters**

- **x** *(float)* – x coordinate of the point
- **y** *(float)* – y coordinate of the point

**distance_to** *(x[, unit]*)

Calculate the distance to x, which may be `point_like` or `rect_like`. The distance is given in units of either pixels (default), inches, centimeters or millimeters.

**Parameters**

- **x** *(point_like, rect_like)* – to which to compute the distance.
- **unit** *(str)* – the unit to be measured in. One of “px”, “in”, “cm”, “mm”.

**Return type** float

**Returns**

the distance to x. If this is `rect_like`, then the distance

- is the length of the shortest line connecting to one of the rectangle sides
- is calculated to the finite version of it
- is zero if it contains the point

**norm()** *(New in version 1.16.0)*

Return the Euclidean norm (the length) of the point as a vector. Equals result of function `abs()`.

**transform**(m)

Apply a matrix to the point and replace it with the result.

**Parameters** m *(matrix_like)* – The matrix to be applied.

**Return type** Point

**unit**

Result of dividing each coordinate by `norm(point)`, the distance of the point to (0,0). This is a vector of length 1 pointing in the same direction as the point does. Its x, resp. y values are equal to the cosine, resp. sine of the angle this vector (and the point itself) has with the x axis.
Type `Point`

`abs_unit`

Same as `unit` above, replacing the coordinates with their absolute values.

Type `Point`

`x`

The x coordinate

Type `float`

`y`

The y coordinate

Type `float`

Note:

- This class adheres to the Python sequence protocol, so components can be accessed via their index, too. Also refer to Using Python Sequences as Arguments in PyMuPDF.

- Rectangles can be used with arithmetic operators – see chapter Operator Algebra for Geometry Objects.

### 6.15 Quad

Represents a four-sided mathematical shape (also called “quadrilateral” or “tetragon”) in the plane, defined as a sequence of four `Point` objects ul, ur, ll, lr (conveniently called upper left, upper right, lower left, lower right).

Quads can be obtained as results of text search methods (`Page.search_for()`), and they are used to define text marker annotations (see e.g. `Page.addSquigglyAnnot()` and friends), and in several draw methods (like `Page.draw_quad()` / `Shape.draw_quad()`, `Page.draw_oval()`/`Shape.drawQuad()`).

Note:
• If the corners of a rectangle are transformed with a rotation, scale or translation Matrix, then the resulting quad is rectangular, i.e. its corners again enclose angles of 90 degrees. Property Quad.isRectangular checks whether a quad can be thought of being the result of such an operation.

• This is not true for all matrices: e.g. shear matrices produce parallelograms, and non-invertible matrices deliver “degenerate” tetragons like triangles or lines.

• Attribute Quad.rect obtains the envelopping rectangle. Vice versa, rectangles now have attributes Rect.quad, resp. IRect.quad to obtain their respective tetragon versions.

<table>

</tr>
<tr>
<td>Quad.height</td>
<td>the longest height value</td>
</tr>
</tbody>
</table>

Class API

class Quad

    __init__(self)
    __init__(self, ul, ur, ll, lr)
    __init__(self, quad)
    __init__(self, sequence)

Overloaded constructors: “ul”, “ur”, “ll”, “lr” stand for point_like objects (the four corners), “sequence” is a Python sequence with four point_like objects.

If “quad” is specified, the constructor creates a new copy of it.

Without parameters, a quad consisting of 4 copies of Point(0, 0) is created.

transform(matrix)
Modify the quadrilateral by transforming each of its corners with a matrix.

    Parameters matrix(matrix_like) – the matrix.

morph(fixpoint, matrix)
(New in version 1.17.0) “Morph” the quad with a matrix-like using a point-like as fixed point.

    Parameters

    • fixpoint(point_like) – the point.

    • matrix(matrix_like) – the matrix.

    Returns

    a new quad. The effect is achieved by using the following code:
So the quad is translated such, that fixpoint becomes the origin (0, 0), then the matrix is applied to it, and finally a reverse translation is done.

Typical uses include rotating the quad around a desired point.

**rect**

The smallest rectangle containing the quad, represented by the blue area in the following picture.

Type **Rect**

**ul**

Upper left point.

Type **Point**

**ur**

Upper right point.

Type **Point**

**ll**

Lower left point.

Type **Point**

**lr**

Lower right point.

Type **Point**

**isConvex**

(New in version 1.16.1)

True if every line connecting two points of the quad is inside the quad. We in addition also make sure here, that the quad is not “degenerate”, i.e. not all corners are on the same line (which would still qualify as convexity in the mathematical sense).
**Type** bool

**isEmpty**
True if enclosed area is zero, which means that at least three of the four corners are on the same line. If this is false, the quad may still be degenerate or not look like a tetragon at all (triangles, parallelograms, trapezoids, ...).

**Type** bool

**isRectangular**
True if all corner angles are 90 degrees. This implies that the quad is **convex and not empty**.

**Type** float

**width**
The maximum length of the top and the bottom side.

**height**
The maximum length of the left and the right side.

### 6.15.1 Remark

This class adheres to the sequence protocol, so components can be dealt with via their indices, too. Also refer to *Using Python Sequences as Arguments in PyMuPDF*.

We are still in process to extend algebraic operations to quads. Multiplication and division with / by numbers and matrices are already defined. Addition, subtraction and any unary operations may follow when we see an actual need.

### 6.16 Rect

*Rect* represents a rectangle defined by four floating point numbers `x0, y0, x1, y1`. They are treated as being coordinates of two diagonally opposite points. The first two numbers are regarded as the “top left” corner `P_{x0,y0}` and `P_{x1,y1}` as the “bottom right” one. However, these two properties need not coincide with their intuitive meanings – read on.

The following remarks are also valid for *IRect* objects:

- Rectangle borders are always parallel to the respective X- and Y-axes.
- The constructing points can be anywhere in the plane – they need not even be different, and e.g. “top left” need not be the geometrical “north-western” point.
- For any given quadruple of numbers, the geometrically “same” rectangle can be defined in (up to) four different ways: `Rect(P_{x0,y0}, P_{x1,y1})`, `Rect(P_{x1,y1}, P_{x0,y0})`, `Rect(P_{x0,y1}, P_{x1,y0})`, and `Rect(P_{x1,y0}, P_{x0,y1})`.

Hence some useful classification:

- A rectangle is called **finite** if `x0 <= x1` and `y0 <= y1` (i.e. the bottom right point is “south-eastern” to the top left one), otherwise **infinite**. Of the four alternatives above, **only one** is finite (disregarding degenerate cases). Please take into account, that in MuPDF’s coordinate system the y-axis is oriented from **top to bottom**.
- A rectangle is called **empty** if `x0 = x1` or `y0 = y1`, i.e. if its area is zero.

**Note:** It sounds like a paradox: a rectangle can be both, infinite and empty . . .

</tbody>
</table>

## Class API

```python
class Rect

    __init__(self)
    __init__(self, x0, y0, x1, y1)
    __init__(self, top_left, bottom_right)
    __init__(self, top_left, x1, y1)
    __init__(self, x0, y0, bottom_right)
    __init__(self, rect)
    __init__(self, sequence)

Overloaded constructors: `top_left, bottom_right` stand for `point_like` objects, ”sequence” is a Python sequence type of 4 numbers (see Using Python Sequences as Arguments in PyMuPDF), “rect” means another `rect_like`, while the other parameters mean coordinates.

If “rect” is specified, the constructor creates a new copy of it.

Without parameters, the empty rectangle `Rect(0.0, 0.0, 0.0, 0.0)` is created.

```

## round()

Creates the smallest containing `IRect`, This is not the same as simply rounding the rectangle’s edges: The top left corner is rounded upwards and left while the bottom right corner is rounded downwards and to the right.

---

200 Chapter 6. Classes
1. If the rectangle is infinite, the “normalized” (finite) version of it will be taken. The result of this method is always a finite IRect.

2. If the rectangle is empty, the result is also empty.

3. Possible paradox: The result may be empty, even if the rectangle is not empty! In such cases, the result obviously does not contain the rectangle. This is because MuPDF’s algorithm allows for a small tolerance (1e-3). Example:

   ```python
   >>> r = fitz.Rect(100, 100, 200, 100.001)
   >>> r.isEmpty  # rect is NOT empty
   False
   >>> r.round()  # but its irect IS empty!
   fitz.IRect(100, 100, 200, 100)
   >>> r.round().isEmpty
   True
   ```

Return type IRect

**transform**(*m*)

Transforms the rectangle with a matrix and replaces the original. If the rectangle is empty or infinite, this is a no-operation.

**Parameters**

- **m** *(Matrix)* – The matrix for the transformation.

**Return type** Rect

**Returns** the smallest rectangle that contains the transformed original.

**intersect**(*r*)

The intersection (common rectangular area) of the current rectangle and *r* is calculated and replaces the current rectangle. If either rectangle is empty, the result is also empty. If *r* is infinite, this is a no-operation.

**Parameters**

- **r** *(Rect)* – Second rectangle

**includeRect**(*r*)

The smallest rectangle containing the current one and *r* is calculated and replaces the current one. If either rectangle is infinite, the result is also infinite. If one is empty, the other one will be taken as the result.

**Parameters**

- **r** *(Rect)* – Second rectangle

**includePoint**(*p*)

The smallest rectangle containing the current one and point *p* is calculated and replaces the current one. Infinite rectangles remain unchanged. To create a rectangle containing a series of points, start with (the empty) `fitz.Rect(p1, p1)` and successively perform includePoint operations for the other points.

**Parameters**

- **p** *(Point)* – Point to include.

**getRectArea**(*[unit]*)

**getArea**(*[unit]*)

Calculate the area of the rectangle and, with no parameter, equals **abs**(rect). Like an empty rectangle, the area of an infinite rectangle is also zero. So, at least one of `fitz.Rect(p1, p2)` and `fitz.Rect(p2, p1)` has a zero area.
Parameters **unit** *(str)* – Specify required unit: respective squares of *px* (pixels, default), *in* (inches), *cm* (centimeters), or *mm* (millimeters).

**Return type** float

**contains**(x)
Checks whether *x* is contained in the rectangle. It may be an *IRect*, *Rect*, *Point* or number. If *x* is an empty rectangle, this is always true. If the rectangle is empty this is always *False* for all non-empty rectangles and for all points. If *x* is a number, it will be checked against the four components. *x in rect* and *rect.contains(x)* are equivalent.

**Parameters**
- **x** (*IRect* or *Rect* or *Point* or number) – the object to check.

**Return type** bool

**intersects**(r)
Checks whether the rectangle and a *rect_like* “r” contain a common non-empty *Rect*. This will always be *False* if either is infinite or empty.

**Parameters**
- **r** (*rect_like*) – the rectangle to check.

**Return type** bool

**morph**(fixpoint, matrix)
*(New in version 1.17.0)*

Return a new quad after applying a matrix to it using a fixed point.

**Parameters**
- **fixpoint** (*point_like*) – the fixed point.
- **matrix** (*matrix_like*) – the matrix.

**Returns** a new *Quad*. This a wrapper for the same-named quad method.

**norm**()
*(New in version 1.16.0)*

Return the Euclidean norm of the rectangle treated as a vector of four numbers.

**normalize**()
Replace the rectangle with its finite version. This is done by shuffling the rectangle corners. After completion of this method, the bottom right corner will indeed be south-eastern to the top left one.

**irect**
Equals result of method *round()*.

**top_left**

**tl**
Equals *Point(x0, y0)*.

**Type** *Point*

**top_right**

**tr**
Equals *Point(x1, y0)*.

**Type** *Point*

**bottom_left**

**bl**
Equals *Point(x0, y1)*.
Type `Point`

**bottom_right**

*br*

Equals `Point(x1, y1)`.

Type `Point`

**quad**

The quadrilateral `Quad(rect.tl, rect.tr, rect.bl, rect.br)`.

Type `Quad`

**width**

Width of the rectangle. Equals `abs(x1 - x0)`.

*Return type* `float`

**height**

Height of the rectangle. Equals `abs(y1 - y0)`.

*Return type* `float`

**x0**

X-coordinate of the left corners.

Type `float`

**y0**

Y-coordinate of the top corners.

Type `float`

**x1**

X-coordinate of the right corners.

Type `float`

**y1**

Y-coordinate of the bottom corners.

Type `float`

**isInfinite**

*True* if rectangle is infinite, *False* otherwise.

Type `bool`

**isEmpty**

*True* if rectangle is empty, *False* otherwise.

Type `bool`

---

**Note:**

- This class adheres to the Python sequence protocol, so components can be accessed via their index, too. Also refer to [Using Python Sequences as Arguments in PyMuPDF](https://pympdf.readthedocs.io/en/latest/using-sequences-as-arguments.html).
- Rectangles can be used with arithmetic operators – see chapter [Operator Algebra for Geometry Objects](https://pympdf.readthedocs.io/en/latest/operator-algebra.html).
6.17 Shape

This class allows creating interconnected graphical elements on a PDF page. Its methods have the same meaning and name as the corresponding `Page` methods.

In fact, each `Page` draw method is just a convenience wrapper for (1) one shape draw method, (2) the `finish()` method, and (3) the `commit()` method. For page text insertion, only the `commit()` method is invoked. If many draw and text operations are executed for a page, you should always consider using a `Shape` object.

Several draw methods can be executed in a row and each one of them will contribute to one drawing. Once the drawing is complete, the `finish()` method must be invoked to apply color, dashing, width, morphing and other attributes.

**Draw** methods of this class (and `insert_textbox()`) are logging the area they are covering in a rectangle (`Shape.rect`). This property can for instance be used to set `Page.CropBox`.

**Text insertions** `insert_text()` and `insert_textbox()` implicitly execute a “finish” and therefore only require `commit()` to become effective. As a consequence, both include parameters for controlling properties like colors, etc.

Class API

class Shape

```python
__init__(self, page)
```

Create a new drawing. During importing PyMuPDF, the `fitz.Page` object is being given the convenience method `newShape()` to construct a `Shape` object. During instantiation, a check will be made whether we do have a PDF page. An exception is otherwise raised.

**Parameters** `page` (`Page`) – an existing page of a PDF document.
**draw_line**(*p1*, *p2*)

Draw a line from *point_like* objects *p1* to *p2*.

**Parameters**

- **p1** (*point_like*) – starting point
- **p2** (*point_like*) – end point

**Return type** *Point*

**Returns** the end point, *p2*.

**draw_squiggle**(*p1*, *p2*, *breadth=2*)

Draw a squiggly (wavy, undulated) line from *point_like* objects *p1* to *p2*. An integer number of full wave periods will always be drawn, one period having a length of 4 * breadth*. The breadth parameter will be adjusted as necessary to meet this condition. The drawn line will always turn “left” when leaving *p1* and always join *p2* from the “right”.

**Parameters**

- **p1** (*point_like*) – starting point
- **p2** (*point_like*) – end point
- **breadth** (*float*) – the amplitude of each wave. The condition 2 * breadth < abs(*p2* - *p1*) must be true to fit in at least one wave. See the following picture, which shows two points connected by one full period.

**Return type** *Point*

**Returns** the end point, *p2*.

Here is an example of three connected lines, forming a closed, filled triangle. Little arrows indicate the stroking direction.
Note: Waves drawn are not trigonometric (sine / cosine). If you need that, have a look at draw-sines.py.

draw_zigzag(p1, p2, breadth=2)
Draw a zigzag line from point_like objects p1 to p2. An integer number of full zigzag periods will always be drawn, one period having a length of 4 * breadth. The breadth parameter will be adjusted to meet this condition. The drawn line will always turn “left” when leaving p1 and always join p2 from the “right”.

Parameters
- **p1** (point_like) – starting point
- **p2** (point_like) – end point
- **breadth** (float) – the amplitude of the movement. The condition 2 * breadth < abs(p2 - p1) must be true to fit in at least one period.

Return type **Point**

Returns the end point, p2.

draw_polyline(points)
Draw several connected lines between points contained in the sequence points. This can be used for creating arbitrary polygons by setting the last item equal to the first one.

Parameters **points** (sequence) – a sequence of point_like objects. Its length must at least be 2 (in which case it is equivalent to draw_line()).

Return type **Point**

Returns points[-1] – the last point in the argument sequence.

draw_bezier(p1, p2, p3, p4)
Draw a standard cubic Bézier curve from p1 to p4, using p2 and p3 as control points.

All arguments are point_likes.

Return type **Point**
**Returns** the end point, \( p4 \).

**Note:** The points do not need to be different – experiment a bit with some of them being equal!

Example:

```
\begin{figure}
\centering
\includegraphics[width=0.8\textwidth]{example.png}
\caption{Example of \texttt{draw_oval} and \texttt{draw_bezier}.
\texttt{draw_bezier(P1, P2, P3, P4)}
\texttt{finish(color=red, fill=yellow, closePath=False)}
\end{figure}
```

draw_oval \((\texttt{tetra})\)

Draw an “ellipse” inside the given tetragon (quadrilateral). If it is a square, a regular circle is drawn, a general rectangle will result in an ellipse. If a quadrilateral is used instead, a plethora of shapes can be the result.

The drawing starts and ends at the middle point of the line connecting bottom-left and top-left corners in an anti-clockwise movement.

**Parameters** \( \texttt{tetra} (\texttt{rect_like, quad_like}) = \texttt{rect_like} \) or \( \texttt{quad_like} \).

*Changed in version 1.14.5:* tetragons are now also supported.

**Return type** \( \texttt{Point} \)

**Returns** the middle point of line from \( \texttt{rect.bl} \) to \( \texttt{rect.tl} \), or from \( \texttt{quad.ll} \) to \( \texttt{quad.ul} \), respectively. Look at just a few examples here, or at the \texttt{quad-show?.py} scripts in the PyMuPDF-Utilities repository.

```
\begin{figure}
\centering
\includegraphics[width=0.8\textwidth]{example.png}
\caption{Examples of \texttt{draw_oval}.
\texttt{draw_oval(tetra)}
\end{figure}
```

draw_circle \((\texttt{center, radius})\)

Draw a circle given its center and radius. The drawing starts and ends at point \( \texttt{center - (radius, 0)} \) in an anti-clockwise movement. This corresponds to the middle point of the enclosing rectangle’s left side.

The method is a shortcut for \texttt{draw_sector(center, start, 360, fullSector=False)}. To draw a circle in a clockwise movement, change the sign of the degree.

**Parameters**

- \( \texttt{center (point_like)} \) – the center of the circle.
• **radius** (*float*) – the radius of the circle. Must be positive.

**Return type**  *Point*  
**Returns**  *center* - (*radius*, 0).

**draw_curve** (*p1*, *p2*, *p3*)

A special case of **drawBezier()**: Draw a cubic Bezier curve from *p1* to *p3*. On each of the two lines from *p1* to *p2* and from *p2* to *p3* one control point is generated. This guarantees that the curve’s curvature does not change its sign. If these two connecting lines intersect with an angle of 90 degrees, then the resulting curve is a quarter ellipse (or quarter circle, if of same length) circumference.

All arguments are **point_like**.

**Return type**  *Point*  
**Returns**  the end point, *p3*.

Example: a filled quarter ellipse segment.

```python
draw_curve(P1, P2, P3)  
finish(color=red, fill=yellow,  
closePath=False)
```

**draw_sector** (*center*, *point*, *angle*, *fullSector=True*)

Draw a circular sector, optionally connecting the arc to the circle’s center (like a piece of pie).

**Parameters**

• **center** (*point_like*) – the center of the circle.

• **point** (*point_like*) – one of the two end points of the pie’s arc segment. The other one is calculated from the **angle**.

• **angle** (*float*) – the angle of the sector in degrees. Used to calculate the other end point of the arc. Depending on its sign, the arc is drawn anti-clockwise (positive) or clockwise.

• **fullSector** (*bool*) – whether to draw connecting lines from the ends of the arc to the circle center. If a fill color is specified, the full “pie” is colored, otherwise just the sector.

**Returns**  the other end point of the arc. Can be used as starting point for a following invocation to create logically connected pies charts.
Return type *Point*

Examples:

```python
draw_sector(C, P, 90, fullSector=True)
finish(color=red, fill=yellow)
```

```python
draw_sector(C, P, 90, fullSector=False)
finish(color=red, fill=yellow, closePath=False)
```

draw_rect *(rect)*

Draw a rectangle. The drawing starts and ends at the top-left corner in an anti-clockwise movement.

**Parameters**

* rect *(rect_like)* – where to put the rectangle on the page.

**Return type** *Point*

**Returns** top-left corner of the rectangle.

draw_quad *(quad)*

Draw a quadrilateral. The drawing starts and ends at the top-left corner *(Quad.ul)* in an anti-clockwise movement. It invokes `draw_polyline()` with the argument `[ul, ll, lr, ur, ul]`.

**Parameters**

* quad *(quad_like)* – where to put the tetragon on the page.

**Return type** *Point*

**Returns** *Quad.ul*.

insert_text *(point, text, fontsize=11, fontname="helv", fontfile=None, set_simple=False, encoding=TEXT_ENCODING_LATIN, color=None, fill=None, render_mode=0, border_width=1, rotate=0, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)*

Insert text lines start at *point*.

**Parameters**

* point *(point_like)* – the bottom-left position of the first character of *text* in pixels. It is important to understand, how this works in conjunction with the *rotate* parameter. Please have a look at the following picture. The small red dots indicate the posi-
tions of point in each of the four possible cases.

- **text**(str/sequence) – the text to be inserted. May be specified as either a string type or as a sequence type. For sequences, or strings containing line breaks \( n \), several lines will be inserted. No care will be taken if lines are too wide, but the number of inserted lines will be limited by “vertical” space on the page (in the sense of reading direction as established by the rotate parameter). Any rest of text is discarded – the return code however contains the number of inserted lines.

- **stroke_opacity**(float) – (new in v1.18.1) set transparency for stroke colors. Negative values and values > 1 will be ignored. Default is 1 (intransparent).

- **fill_opacity**(float) – (new in v1.18.1) set transparency for fill colors. Default is 1 (intransparent). Use this value to control transparency of the text color. Stroke opacity only affects the border line of characters.

- **rotate**(int) – determines whether to rotate the text. Acceptable values are multiples of 90 degrees. Default is 0 (no rotation), meaning horizontal text lines oriented from left to right. 180 means text is shown upside down from right to left. 90 means anti-clockwise rotation, text running upwards. 270 (or -90) means clockwise rotation, text running downwards. In any case, point specifies the bottom-left coordinates of the first character’s rectangle. Multiple lines, if present, always follow the reading direction established by this parameter. So line 2 is located above line 1 in case of rotate = 180, etc.

- **oc**(int) – (new in v1.18.4) the xref number of an OCG or OCMD to make this text conditionally displayable.

**Return type** int

**Returns** number of lines inserted.

For a description of the other parameters see *Common Parameters*.

```python
insertTextbox(rect, buffer, fontsize=11, fontname="helv", fontfile=None, set_simple=False, encoding=TEXT_ENCODING_LATIN, color=None, fill=None, render_mode=0, border_width=1, expandtabs=8, align=TEXT_ALIGN_LEFT, rotate=0, morph=None, stroke_opacity=1, fill_opacity=1, oc=0)
```

PDF only: Insert text into the specified rectangle. The text will be split into lines and words and then filled into the available space, starting from one of the four rectangle corners, which depends on rotate. Line feeds will be respected as well as multiple spaces will be.

**Parameters**

- **rect**(rect_like) – the area to use. It must be finite and not empty.
• **buffer**(str/sequence) – the text to be inserted. Must be specified as a string or a sequence of strings. Line breaks are respected also when occurring in a sequence entry.

• **align**(int) – align each text line. Default is 0 (left). Centered, right and justified are the other supported options, see *Text Alignment*. Please note that the effect of parameter value TEXT_ALIGN_JUSTIFY is only achievable with “simple” (single-byte) fonts (including the PDF Base 14 Fonts). Refer to Adobe PDF References, section 5.2.2, page 399.

• **expandtabs**(int) – controls handling of tab characters \(t\) using the *string.expandtabs() method per each line.*

• **stroke_opacity**(float) – *(new in v1.18.1)* set transparency for stroke colors. Negative values and values \(> 1\) will be ignored. Default is \(1\) (intransparent).

• **fill_opacity**(float) – *(new in v1.18.1)* set transparency for fill colors. Default is \(1\) (intransparent). Use this value to control transparency of the text color. Stroke opacity only affects the border line of characters.

• **rotate**(int) – requests text to be rotated in the rectangle. This value must be a multiple of 90 degrees. Default is 0 (no rotation). Effectively, four different values are processed: 0, 90, 180 and 270 (= -90), each causing the text to start in a different rectangle corner. Bottom-left is 90, bottom-right is 180, and -90 / 270 is top-right. See the example how text is filled in a rectangle. This argument takes precedence over morphing. See the second example, which shows text first rotated left by 90 degrees and then the whole rectangle rotated clockwise around is lower left corner.

• **oc**(int) – *(new in v1.18.4)* the *xref number of an OCG or OCMD* to make this text conditionally displayable.

**Return type** float

**Returns**

**If positive or zero:** successful execution. The value returned is the unused rectangle line space in pixels. This may safely be ignored – or be used to optimize the rectangle, position subsequent items, etc.

**If negative:** no execution. The value returned is the space deficit to store text lines. Enlarge rectangle, decrease *fontsize*, decrease text amount, etc.
For a description of the other parameters see Common Parameters.

**finish**(*width=*1, *color=None, fill=None, lineCap=0, lineJoin=0, dashes=None, closePath=True, even_odd=False, morph=(fixpoint, matrix), stroke_opacity=1, fill_opacity=1, oc=0*)

Finish a set of draw*() methods by applying Common Parameters to all of them. This method also supports morphing the resulting compound drawing using a fixpoint Point.

**Parameters**

- **morph** (*sequence*) – morph the text or the compound drawing around some arbitrary Point fixpoint by applying Matrix matrix to it. This implies that fixpoint is a fixed point of this operation: it will not change its position. Default is no morphing (None). The matrix can contain any values in its first 4 components, matrix.e == matrix.f == 0 must be true, however. This means that any combination of scaling, shearing, rotating, flipping, etc. is possible, but translations are not.

- **stroke_opacity** (*float*) – (new in v1.18.1) set transparency for stroke colors. Value < 0 or > 1 will be ignored. Default is 1 (intransparent).

- **fill_opacity** (*float*) – (new in v1.18.1) set transparency for fill colors. Default is 1 (intransparent).

- **even_odd** (*bool*) – request the “even-odd rule” for filling operations. Default is False, so that the “nonzero winding number rule” is used. These rules are alternative methods to apply the fill color where areas overlap. Only with fairly complex shapes a different behavior is to be expected with these rules. For an in-depth explanation, see Adobe PDF References, pp. 232 ff. Here is an example to demonstrate the difference.

- **oc** (*int*) – (new in v1.18.4) the xref number of an OCG or OCMD to make this drawing conditionally displayable.
Note: For each pixel in a drawing the following will happen:

1. Rule “even-odd” counts, how many areas are overlapping at a pixel. If this count is odd the pixel is regarded inside, if it is even, the pixel is outside.

2. Default rule “nonzero winding” also looks at the orientation of overlapping areas: it adds 1 if an area is drawn anti-clockwise and it subtracts 1 for clockwise areas. If the result is zero, the pixel is regarded outside, pixels with a non-zero count are inside.

In the top two shapes, three circles are drawn in standard manner (anti-clockwise, look at the arrows). The lower two shapes contain one (top-left) circle drawn clockwise. As can be seen, area orientation is irrelevant for the even-odd rule.

commit (overlay=True)
Update the page’s contents with the accumulated draw commands and text insertions. If a Shape is not committed, the page will not be changed.

The method will reset attributes Shape.rect, lastPoint, draw_cont, text_cont and totalcont. Afterwards, the shape object can be reused for the same page.
Parameters `overlay` *(bool)* – determine whether to put content in foreground (default) or background. Relevant only, if the page already has a non-empty `contents` object.

`doc`
For reference only: the page’s document.
  
  **Type** `Document`

`page`
For reference only: the owning page.
  
  **Type** `Page`

`height`
Copy of the page’s height
  
  **Type** `float`

`width`
Copy of the page’s width.
  
  **Type** `float`

`draw_cont`
Accumulated command buffer for `draw` methods since last finish.
  
  **Type** `str`

`text_cont`
Accumulated text buffer. All text insertions go here. On `commit()` this buffer will be appended to `totalcont`, so that text will never be covered by drawings in the same `Shape`.
  
  **Type** `str`

`rect`
Rectangle surrounding drawings. This attribute is at your disposal and may be changed at any time. Its value is set to `None` when a shape is created or committed. Every `draw`* method, and `Shape.insert_textbox()` update this property (i.e. *enlarge* the rectangle as needed). Morphing operations, however (`Shape.finish()`, `Shape.insert_textbox()`) are ignored.

A typical use of this attribute would be setting `Page.CropBox` to this value, when you are creating shapes for later or external use. If you have not manipulated the attribute yourself, it should reflect a rectangle that contains all drawings so far.

If you have used morphing and need a rectangle containing the morphed objects, use the following code:

```python
>>> # assuming ...
>>> matrix = (point, matrix)
>>> # ... recalculate the shape rectangle like so:
>>> shape.rect = (shape.rect - fitz.Rect(point, point)) * ~matrix + fitz.Rect(point, point)
```

  **Type** `Rect`

`totalcont`
Total accumulated command buffer for draws and text insertions. This will be used by `Shape.commit()`.
  
  **Type** `str`

`lastPoint`
For reference only: the current point of the drawing path. It is `None` at `Shape` creation and after each `finish()` and `commit()`.
6.17.1 Usage

A drawing object is constructed by \texttt{shape = page.newShape()}. After this, as many draw, finish and text insertions methods as required may follow. Each sequence of draws must be finished before the drawing is committed. The overall coding pattern looks like this:

```python
>>> shape = page.new_shape()
>>> shape.draw1(...)
>>> shape.draw2(...)
>>> ...  
>>> shape.finish(width=..., color=..., fill=..., morph=...)
>>> shape.draw3(...)
>>> shape.draw4(...)
>>> ...  
>>> shape.insert_text*
>>> ...  
>>> shape.commit()
>>> ....
```

Note:

1. Each \texttt{finish()} combines the preceding draws into one logical shape, giving it common colors, line width, morphing, etc. If \texttt{closePath} is specified, it will also connect the end point of the last draw with the starting point of the first one.

2. To successfully create compound graphics, let each draw method use the end point of the previous one as its starting point. In the above pseudo code, \texttt{draw2} should hence use the returned \texttt{Point} of \texttt{draw1} as its starting point. Failing to do so, would automatically start a new path and \texttt{finish()} may not work as expected (but it won’t complain either).

3. Text insertions may occur anywhere before the commit (they neither touch \texttt{Shape.draw_cont} nor \texttt{Shape.lastPoint}). They are appended to \texttt{Shape.totalcont} directly, whereas draws will be appended by \texttt{Shape.finish}.

4. Each \texttt{commit} takes all text insertions and shapes and places them in foreground or background on the page – thus providing a way to control graphical layers.

5. \textbf{Only commit will update} the page’s contents, the other methods are basically string manipulations.

6.17.2 Examples

1. Create a full circle of pieces of pie in different colors:

```python
shape = page.new_shape()  # start a new shape
cols = (...)  # a sequence of RGB color triples
pieces = len(cols)  # number of pieces to draw
beta = 360. / pieces  # angle of each piece of pie
center = fitz.Point(...)  # center of the pie
p0 = fitz.Point(...)  # starting point
for i in range(pieces):
    p0 = shape.draw_sector(center, p0, beta,
```

(continues on next page)
Here is an example for 5 colors:

Here is the polygon for \( n = 7 \):

### 6.17.3 Common Parameters

- **fontname** *(str)*
In general, there are three options:

1. Use one of the standard PDF Base 14 Fonts. In this case, \texttt{fontfile} \textbf{must not} be specified and “\texttt{Helvetica}” is used if this parameter is omitted, too.

2. Choose a font already in use by the page. Then specify its \texttt{reference} name prefixed with a slash “/”, see example below.

3. Specify a font file present on your system. In this case choose an arbitrary, but new name for this parameter (without “/” prefix).

If inserted text should re-use one of the page’s fonts, use its reference name appearing in \texttt{get_fonts()} like so:

Suppose the font list has the item \{1024, 0, ‘Type1’, ‘NimbusMonL-Bold’, ‘R366’\}, then specify \texttt{fontname = ”/R366”, fontfile = None} to use font \texttt{NimbusMonL-Bold}.

---

\textbf{fontfile (str)}

File path of a font existing on your computer. If you specify \texttt{fontfile}, make sure you use a \texttt{fontname} \textbf{not occurring} in the above list. This new font will be embedded in the PDF upon \texttt{doc.save()}. Similar to new images, a font file will be embedded only once. A table of MD5 codes for the binary font contents is used to ensure this.

---

\textbf{set_simple (bool)}

Fonts installed from files are installed as \texttt{Type0} fonts by default. If you want to use 1-byte characters only, set this to true. This setting cannot be reverted. Subsequent changes are ignored.

---

\textbf{fontsize (float)}

Font size of text. This also determines the line height as \texttt{fontsize * 1.2}.

---

\textbf{dashes (str)}

Causes lines to be drawn dashed. The general format is "\{n m\} p". The square brackets denote a PDF array of one or two floats. Float p is called the “dash phase” and specifies how many pixels should be skipped before the dashing starts.

A continuous line (no dashes) is drawn with "[\] 0" or \texttt{None} or "". Specifying "[3 4] 0" means dashes of 3 and gaps of 4 pixels following each other. "[3 3] 0" and "[3] 0" do the same thing. For (the rather complex) details on how to achieve sophisticated dashing effects, see \textit{Adobe PDF References}, page 217.

---

\textbf{color / fill (list, tuple)}

Line and fill colors can be specified as tuples or list of of floats from 0 to 1. These sequences must have a length of 1 (GRAY), 3 (RGB) or 4 (CMYK). For GRAY colorspace, a single float instead of the unwieldy \texttt{float} or \texttt{list} is also accepted.

To simplify color specification, method \texttt{getColor()} in \texttt{fitz.utils} may be used to get predefined RGB color triples by name. It accepts a string as the name of the color and returns the corresponding triple. The method knows over 540 color names – see section \textit{Color Database}.

Please note that the term \texttt{color} usually means “stroke” color when used in conjunction with fill color.
stroke_opacity / fill_opacity (floats)

Both values are floats in range [0, 1]. Negative values or values > 1 will ignored (in most cases). Both set the transparency such that a value 0.5 corresponds to 50% transparency, 0 means invisible and 1 means intransparent. For e.g. a rectangle the stroke opacity applies to its border and fill opacity to its interior.

For text insertions (Shape.insert_text() and Shape.insert_textbox()), use fill_opacity for the text. At first sight this seems surprising, but it becomes obvious when you look further down to render_mode: fill_opacity applies to the yellow and stroke.opacity applies to the blue color.

border_width (float)

Set the border width for text insertions. New in v1.14.9. Relevant only if the render mode argument is used with a value greater zero.

render_mode (int)

New in version 1.14.9: Integer in range(8) which controls the text appearance (Shape.insert_text() and Shape.insert_textbox()). See page 398 in Adobe PDF References. New in v1.14.9. These methods now also differentiate between fill and stroke colors.

- For default 0, only the text fill color is used to paint the text. For backward compatibility, using the color parameter instead also works.
- For render mode 1, only the border of each glyph (i.e. text character) is drawn with a thickness as set in argument border_width. The color chosen in the color argument is taken for this, the fill parameter is ignored.
- For render mode 2, the glyphs are filled and stroked, using both color parameters and the specified border width. You can use this value to simulate bold text without using another font: choose the same value for fill and color and an appropriate value for border_width.
- For render mode 3, the glyphs are neither stroked nor filled: the text becomes invisible.

The following examples use border_width=0.3, together with a fontsize of 15. Stroke color is blue and fill color is some yellow.

overlay (bool)

Causes the item to appear in foreground (default) or background.
morph (sequence)

Causes “morphing” of either a shape, created by the \texttt{draw*()} methods, or the text inserted by page methods \texttt{insert_textbox()} / \texttt{insert_text()}. If not \texttt{None}, it must be a pair (\texttt{fixpoint}, \texttt{matrix}), where \texttt{fixpoint} is a \texttt{Point} and \texttt{matrix} is a \texttt{Matrix}. The matrix can be anything except translations, i.e. \texttt{matrix.e == matrix.f == 0} must be true. The point is used as a fixed point for the matrix operation. For example, if \texttt{matrix} is a rotation or scaling, then \texttt{fixpoint} is its center. Similarly, if \texttt{matrix} is a left-right or up-down flip, then the mirroring axis will be the vertical, respectively horizontal line going through \texttt{fixpoint}, etc.

\textbf{Note:} Several methods contain checks whether the to be inserted items will actually fit into the page (like \texttt{Shape.insert_text()}, or \texttt{Shape.draw_rect()}). For the result of a morphing operation there is however no such guaranty: this is entirely the programmer’s responsibility.

lineCap (deprecated: “roundCap”) (int)

Controls the look of line ends. The default value 0 lets each line end at exactly the given coordinate in a sharp edge. A value of 1 adds a semi-circle to the ends, whose center is the end point and whose diameter is the line width. Value 2 adds a semi-square with an edge length of line width and a center of the line end.

\textit{Changed in version 1.14.15}

lineJoin (int)

\textit{New in version 1.14.15}: Controls the way how line connections look like. This may be either as a sharp edge (0), a rounded join (1), or a cut-off edge (2, “butt”).

closePath (bool)

Causes the end point of a drawing to be automatically connected with the starting point (by a straight line).

6.18 TextPage

This class represents text and images shown on a document page. All MuPDF document types are supported.

The usual ways to create a textpage are \texttt{DisplayList.get_textpage()} and \texttt{Page.get_textpage()}. Because there is a limited set of methods in this class, there exist wrappers in the \texttt{Page} class, which incorporate creating an intermediate text page and then invoke one of the following methods. The last column of this table shows these corresponding \texttt{Page} methods.

For a description of what this class is all about, see Appendix 2.

Class API

```python
class TextPage

    extractText()
    extractTEXT()
        Return a string of the page’s complete text. The text is UTF-8 unicode and in the same sequence as specified at the time of document creation.
        
        **Return type**  str

    extractBLOCKS()
        Textpage content as a list of text lines grouped by block. Each list items looks like this:
        
        ```
        (x0, y0, x1, y1, "lines in blocks", block_no, block_type)
        ```
        
        The first four entries are the block’s bbox coordinates, `block_type` is 1 for an image block, 0 for text. `block_no` is the block sequence number.
        
        For an image block, its bbox and a text line with image meta information is included – not the image data itself.
        
        This is a high-speed method with just enough information to output plain text in desired reading sequence.
        
        **Return type**  list

    extractWORDS()
        Textpage content as a list of single words with bbox information. An item of this list looks like this:
        
        ```
        (x0, y0, x1, y1, "word", block_no, line_no, word_no)
        ```
        
        Everything wrapped in spaces is treated as a “word” with this method.
        
        This is a high-speed method which e.g. allows extracting text from within a given rectangle.
        
        **Return type**  list

    extractHTML()
        Textpage content in HTML format. This version contains complete formatting and positioning information. Images are included (encoded as base64 strings). You need an HTML package to interpret the output in Python. Your internet browser should be able to adequately display this information, but see `Controlling Quality of HTML Output`.
        
        **Return type**  str
```
extractDICT()
Textpage content as a Python dictionary. Provides same information detail as HTML. See below for the structure.

Return type dict

extractJSON()
Textpage content in JSON format. Created by json.dumps(TextPage.extractDICT()). It is included for backlevel compatibility. You will probably use this method ever only for outputting the result to some file. The method detects binary image data and converts them to base64 encoded strings on JSON output.

Return type str

extractXHTML()
Textpage content in XHTML format. Text information detail is comparable with extractTEXT(), but also contains images (base64 encoded). This method makes no attempt to re-create the original visual appearance.

Return type str

extractXML()
Textpage content in XML format. This contains complete formatting information about every single character on the page: font, size, line, paragraph, location, color, etc. Contains no images. You probably need an XML package to interpret the output in Python.

Return type str

extractRAWDICT()
Textpage content as a Python dictionary – technically similar to extractDICT(), and it contains that information as a subset (including any images). It provides additional detail down to each character, which makes using XML obsolete in many cases. See below for the structure.

Return type dict

extractRAWJSON()
Textpage content in JSON format. Created by json.dumps(TextPage.extractRAWDICT()). You will probably use this method ever only for outputting the result to some file. The method detects binary image data and converts them to base64 encoded strings on JSON output.

Return type str

search(needle, quads=False)
(Changed in v1.18.2)
Search for string and return a list of found locations.

Parameters

• needle (str) – the string to search for. Upper and lower cases will all match.
• quads (bool) – return quadrilaterals instead of rectangles.

Return type list

Returns a list of Rect or Quad objects, each surrounding a found needle occurrence. The search string may contain spaces, it may therefore happen, that its parts are located on different lines. In this case, more than one rectangle (resp. quadrilateral) are returned.

(Changed in v1.18.2) The method now supports dehyphenation, so it will find “method” even if it was hyphenated in two parts “meth-” and “od” across two lines. The two returned rectangles will exclude the hyphen in this case.

Note: Overview of changes in v1.18.2:
1. The `hit_max` parameter has been removed: all hits are always returned.

2. The `rect` parameter of the `TextPage` is now respected: only text inside this area is examined. Only characters with fully contained bboxes are considered. The wrapper method `Page.search_for()` correspondingly supports a `clip` parameter.

3. Words `hyphenated` at the end of a line are now found.

4. **Overlapping rectangles** in the same line are now automatically joined. We assume that such separations are an artifact created by multiple marked content groups, containing parts of the same search needle.

Example Quad versus Rect: when searching for needle “pymupdf”, then the corresponding entry will either be the blue rectangle, or, if `quads` was specified, the quad $Quad(ul, ur, ll, lr)$.

6.18.1 Dictionary Structure of `extractDICT()` and `extractRAWDICT()`

Visual overview: the TextPage dictionary structure

```
Page: {"width": w, "height": h, "blocks": [blocks]}
```

Image block:
```
{"type": 1, "bbox": (x0, y0, x1, y1), "ext": "png", "width": w, "height": h, "colorspace": n,
"xres": xres, "yres": yres, "bpc": bpc, "image": b"}
```

Text block:
```
{"type": 0, "bbox": (x0, y0, x1, y1), "lines": [lines]}
```

```
Line: {"bbox": (x0, y0, x1, y1), "num": m, "dir": [x, y], "spans": [spans]}
```

```
Span: {"bbox": (x0, y0, x1, y1), "color": sRGB, "font": fontname, "size": fontsize, "flags": fontflags, "text": text}
```

```
Span: {"bbox": (x0, y0, x1, y1), "color": sRGB, "font": fontname, "size": fontsize, "flags": fontflags, "chars": [chars]}
```

```
Char: {"bbox": (x0, y0, x1, y1), "c": character, "origin": (x, y)}
```

6.18.1.1 Page Dictionary

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>width of the clip rectangle (float)</td>
</tr>
<tr>
<td>height</td>
<td>height of the clip rectangle (float)</td>
</tr>
<tr>
<td>blocks</td>
<td>list of block dictionaries</td>
</tr>
</tbody>
</table>

6.18.1.2 Block Dictionaries

Block dictionaries come in two different formats for image blocks and for text blocks.

*(Changed in v1.18.0)* – new dict key `number`, the block number.

Image block:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>1 = image (int)</td>
</tr>
<tr>
<td>bbox</td>
<td>block / image rectangle, formatted as tuple(fitz.Rect)</td>
</tr>
<tr>
<td>number</td>
<td>block number (int) (0-based)</td>
</tr>
<tr>
<td>ext</td>
<td>image type (str), as file extension, see below</td>
</tr>
<tr>
<td>width</td>
<td>original image width (int)</td>
</tr>
<tr>
<td>height</td>
<td>original image height (int)</td>
</tr>
<tr>
<td>colorspace</td>
<td>colorspace.n (int)</td>
</tr>
<tr>
<td>xres</td>
<td>resolution in x-direction (int)</td>
</tr>
<tr>
<td>yres</td>
<td>resolution in y-direction (int)</td>
</tr>
<tr>
<td>bpc</td>
<td>bits per component (int)</td>
</tr>
<tr>
<td>image</td>
<td>image content (bytes or bytearray)</td>
</tr>
</tbody>
</table>
Possible values of the “ext” key are “bmp”, “gif”, “jpeg”, “jp2” (JPEG 2000), “jxr” (JPEG XR), “png”, “pnm”, and “tiff”.

Note:
1. In some error situations, all of the above values may be zero or empty. So, please be prepared to digest items like:

   ```
   {"type": 1, "bbox": (0.0, 0.0, 0.0, 0.0), ..., "image": b""}
   ```

2. `TextPage` and corresponding method `Page.get_text()` are available for all document types. Only for PDF documents, methods `Document.get_page_images()` / `Page.get_images()` offer some overlapping functionality as far as image lists are concerned. But both lists may or may not contain the same items. Any differences are most probably caused by one of the following:

   - “Inline” images (see page 352 of the Adobe PDF References) of a PDF page are contained in a textpage, but not in `Page.get_images()`.
   - Image blocks in a textpage are generated for every image location – whether or not there are any duplicates. This is in contrast to `Page.get_images()`, which will contain each image only once.
   - Images mentioned in the page’s `object` definition will always appear in `Page.get_images()`\(^1\). But it may happen, that there is no “display” command in the page’s `contents` (erroneously or on purpose). In this case the image will not appear in the textpage.

Text block:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>0 = text (int)</td>
</tr>
<tr>
<td>bbox</td>
<td>block rectangle, formatted as tuple(fitz.Rect)</td>
</tr>
<tr>
<td>number</td>
<td>block number (int) (0-based)</td>
</tr>
<tr>
<td>lines</td>
<td>list of text line dictionaries</td>
</tr>
</tbody>
</table>

6.18.1.3 Line Dictionary

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>bbox</td>
<td>line rectangle, formatted as tuple(fitz.Rect)</td>
</tr>
<tr>
<td>wmode</td>
<td>writing mode (int): 0 = horizontal, 1 = vertical</td>
</tr>
<tr>
<td>dir</td>
<td>writing direction (list of floats): [x, y]</td>
</tr>
<tr>
<td>spans</td>
<td>list of span dictionaries</td>
</tr>
</tbody>
</table>

The value of key “dir” is a unit vetor and should be interpreted as follows:

- x: positive = “left-right”, negative = “right-left”, 0 = neither
- y: positive = “top-bottom”, negative = “bottom-top”, 0 = neither

The values indicate the “relative writing speed” in each direction, such that \(x^2 + y^2 = 1\). In other words \(\text{dir} = [\cos(\beta), \sin(\beta)]\), where \(\beta\) is the writing angle relative to the x-axis.

\(^1\) Image specifications for a PDF page are done in a page’s (sub-) dictionary, called “/Resources”. Resource dictionaries can be inherited from the page’s parent object (usually the catalog). The PDF creator may e.g. define one /Resources on file level, naming all images and all fonts ever used by any page. In this case, `Page.get_images()` and `Page.get_fonts()` will always return the same lists for all pages.
6.18.1.4 Span Dictionary

Spans contain the actual text. A line contains more than one span only, if it contains text with different font properties. (Changed in version 1.14.17) Spans now also have a bbox key (again). (Changed in version 1.17.6) Spans now also have an origin key.

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>bbox</td>
<td>span rectangle, formatted as tuple(fitz.Rect)</td>
</tr>
<tr>
<td>origin</td>
<td>tuple coordinates of the first character’s bottom left point</td>
</tr>
<tr>
<td>font</td>
<td>font name (str)</td>
</tr>
<tr>
<td>ascender</td>
<td>ascender of the font (float)</td>
</tr>
<tr>
<td>descender</td>
<td>descender of the font (float)</td>
</tr>
<tr>
<td>size</td>
<td>font size (float)</td>
</tr>
<tr>
<td>flags</td>
<td>font characteristics (int)</td>
</tr>
<tr>
<td>color</td>
<td>text color in sRGB format (int)</td>
</tr>
<tr>
<td>text</td>
<td>(only for extractDICT()) text (str)</td>
</tr>
<tr>
<td>chars</td>
<td>(only for extractRAWDICT()) list of character dictionaries</td>
</tr>
</tbody>
</table>

(New in version 1.16.0): “color” is the text color encoded in sRGB (int) format, e.g. 0xFF0000 for red. There are functions for converting this integer back to formats (r, g, b) (PDF with float values from 0 to 1) sRGB_to_pdf(), or (R, G, B), sRGB_to_rgb() (with integer values from 0 to 255).

(New in v1.18.5): “ascender” and “descender” are font properties, provided relative to fontsize 1. Note that descender is a negative value. The following picture shows the relationship to other values and properties.

These numbers may be used to compute the minimum height of a character (or span) – as opposed to the standard height provided in the “bbox” values (which actually represents the line height). The following code recalculates the span bbox to have a height of fontsize exactly fitting the text inside:

```python
>>> a = span["ascender"]
>>> d = span["descender"]
>>> r = fitz.Rect(span["bbox"])
>>> o = fitz.Point(span["origin"]))  # its y-value is the baseline
>>> r.y1 = o.y - span["size"] * d / (a - d)
>>> r.y0 = r.y1 - span["size"]
>>> # r now is a rectangle of height 'fontsize'
```
Caution: The above calculation may deliver a larger height! This may e.g. happen for OCR-ed documents, where the risk of all sorts of text artifacts is high. MuPDF tries to come up with a reasonable bbox height, independently from the fontsize found in the PDF. So please ensure that the height of `bbox` is larger than `size`.

Note: You may request PyMuPDF to do all of the above automatically by executing `fitz.TOOLS.set_small_glyph_heights(True)`. This sets a global parameter so that all subsequent text searches and text extractions are based on reduced glyph heights, where meaningful.

The following shows the original span rectangle in red and the rectangle with re-computed height in blue.

```
if flags & 2**1: print("italic")
```

6.18.1.5 Character Dictionary for `extractRAWDICT()`

We are currently providing the bbox in `rect_like` format. In a future version, we might change that to `quad_like`.

This image shows the relationship between items in the following table:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>origin</td>
<td>tuple coordinates of the character’s bottom left point</td>
</tr>
<tr>
<td>bbox</td>
<td>character rectangle, formatted as <code>tuple(fitz.Rect)</code></td>
</tr>
<tr>
<td>c</td>
<td>the character (unicode)</td>
</tr>
</tbody>
</table>
6.19 TextWriter

(New in v1.16.18)

This class represents a MuPDF text object. The basic idea is to decouple (1) text preparation, and (2) text output to PDF pages.

During preparation, a text writer stores any number of text pieces (“spans”) together with their positions and individual font information. The output of the writer’s prepared content may happen multiple times to any PDF page with a compatible page size.

A text writer is an elegant alternative to methods `Page.insertText()` and friends:

- **Improved text positioning**: Choose any point where insertion of text should start. Storing text returns the “cursor position” after the last character of the span.

- **Free font choice**: Each text span has its own font and fontsize. This lets you easily switch when composing a larger text.

- **Automatic fallback fonts**: If a character is not supported by the chosen font, alternative fonts are automatically searched. This significantly reduces the risk of seeing unprintable symbols in the output (“TOFUs” – looking like a small rectangle). PyMuPDF now also comes with the universal font “Droid Sans Fallback Regular”, which supports all Latin characters (including Cyrillic and Greek), and all CJK characters (Chinese, Japanese, Korean).

- **Cyrillic and Greek Support**: The PDF Base 14 Fonts have integrated support of Cyrillic and Greek characters without specifying encoding. Your text may be a mixture of Latin, Greek and Cyrillic.

- **Transparency support**: Parameter `opacity` is supported. This offers a handy way to create watermark-style text.

- **Justified text**: Supported for any font – not just simple fonts as in `Page.insertTextbox()`.

- **Reusability**: A TextWriter object exists independent from PDF pages. It can be written multiple times, either to the same or to other pages, in the same or in different PDFs, choosing different colors or transparency.

Using this object entails three steps:

1. When created, a TextWriter requires a fixed page rectangle in relation to which it calculates text positions. A text writer can write to a page with the same size only.

3. Output the TextWriter object on some PDF page.

**Note:**

- Starting with version 1.17.0, TextWriters do support text rotation via the `morph` parameter of `TextWriter.write_text()`.

- There also exists `Page.write_text()` which combines one or more TextWriters and jointly writes them to a given rectangle and with a given rotation angle – much like `Page.show_pdf_page()`.
<table>

Class API

```python
class TextWriter

    __init__(self, rect, opacity=1, color=None)

    Parameters
    ----------
    * rect (rect-like) – rectangle internally used for text positioning computations.
    * opacity (float) – sets the transparency for the text to store here. Values outside the interval [0, 1) will be ignored. A value of e.g. 0.5 means 50% transparency.
    * color (float, sequence) – the color of the text. All colors are specified as floats 0 <= color <= 1. A single float represents some gray level, a sequence implies the colorspace via its length.

    append(pos, text, font=None, fontsize=11, language=None)

    Add some new text in horizontal, left-to-right writing.

    Parameters
    ----------
    * pos (point_like) – start position of the text, the bottom left point of the first character.
    * text (str) – a string (Python 2: unicode is mandatory!) of arbitrary length. It will be written starting at position “pos”.
    * font – a `Font`. If omitted, `fitz.Font("helv")` will be used.
    * fontsize (float) – the fontsize, a positive number, default 11.
    * language (str) – the language to use, e.g. “en” for English. Meaningful values should be compliant with the ISO 639 standards 1, 2, 3 or 5. Reserved for future use: currently has no effect as far as we know.

    Returns
    -------
    text_rect and last_point. *(Changed in v1.18.0:)* Raises an exception for an unsupported font – checked via `Font.isWritable`.

    appendv(pos, text, font=None, fontsize=11, language=None)

    Add some new text in vertical, top-to-bottom writing.

    Parameters
    ----------
    * pos (point_like) – start position of the text, the bottom left point of the first character.
    * text (str) – a string. It will be written starting at position “pos”.
    * font – a `Font`. If omitted, `fitz.Font("helv")` will be used.
```

228 Chapter 6. Classes
• **fontsize** *(float)* – the fontsize, a positive float, default 11.

• **language** *(str)* – the language to use, e.g. “en” for English. Meaningful values should be compliant with the ISO 639 standards 1, 2, 3 or 5. Reserved for future use: currently has no effect as far as we know.

**Returns**  
`text_rect` and `last_point`. *(Changed in v1.18.0:)* Raises an exception for an unsupported font – checked via `Font.isWritable`.

**fill_textbox**( `rect, text, pos=None, font=None, fontsize=11, align=0, warn=True`)  
Fill a given rectangle with text in horizontal, left-to-right manner. This is a convenience method to use as an alternative to `append()`.

**Parameters**  
- **rect** *(rect_like)* – the area to fill. No part of the text will appear outside of this.
- **text** *(str, sequ)* – the text. Can be specified as a (UTF-8) string or a list / tuple of strings. A string will first be converted to a list using `splitlines()` Every list item will begin on a new line (forced line breaks).
- **pos** *(point_like)* – (new in v1.17.3) start storing at this point. Default is a point near rectangle top-left.
- **font** – the `Font`, default `fitz.Font(“helv”)`.
- **fontsize** *(float)* – the fontsize.
- **align** *(int)* – text alignment. Use one of `TEXT_ALIGN_LEFT`, `TEXT_ALIGN_CENTER`, `TEXT_ALIGN_RIGHT` or `TEXT_ALIGN_JUSTIFY`.
- **warn** *(bool)* – warn on text overflow (default), or raise an exception. In any case, text not fitting will not be written.

**Note:**  
Use these methods as often as is required – there is no technical limit (except memory constraints of your system). You can also mix appends and text boxes and have multiple of both. Text positioning is controlled by the insertion point. There is no need to adhere to any order. *(Changed in v1.18.0:)* Raises an exception for an unsupported font – checked via `Font.isWritable`.

**write_text**( `page, opacity=None, color=None, morph=None, overlay=True, oc=0, render_mode=0`)  
Write the TextWriter text to a page.

**Parameters**  
- **page** – write to this `Page`.
- **opacity** *(float)* – override the value of the TextWriter for this output.
- **color** *(sequ)* – override the value of the TextWriter for this output.
- **morph** *(sequ)* – modify the text appearance by applying a matrix to it. If provided, this must be a sequence *(fixpoint, matrix)* with a point-like `fixpoint` and a matrix-like `matrix`. A typical example is rotating the text around `fixpoint`.
- **overlay** *(bool)* – put in foreground (default) or background.
- **oc** *(int)* – (new in v1.18.4) the xref of an OCG or OCMD.
- **render_mode** *(int)* – The PDF Tr operator value.

**text_rect**  
The area currently occupied.
Return type  `Rect`

last_point
The “cursor position” – a `Point` – after the last written character (its bottom-right).

Return type  `Point`

opacity
The text opacity (modifiable).

Return type  `float`

color
The text color (modifiable).

Return type  `float,tuple`

rect
The page rectangle for which this TextWriter was created. Must not be modified.

Return type  `Rect`

---

**Note:** To see some demo scripts dealing with TextWriter, have a look at this repository.

1. Opacity and color apply to **all the text** in this object.

2. If you need different colors / transparency, you must create a separate TextWriter. Whenever you determine the color should change, simply append the text to the respective TextWriter using the previously returned `last_point` as position for the new text span.

3. Appending items or text boxes can occur in arbitrary order: only the position parameter controls where text appears.

4. Font and fontsize can freely vary within the same TextWriter. This can be used to let text with different properties appear on the same displayed line: just specify `pos` accordingly, and e.g. set it to `last_point` of the previously added item.

5. You can use the `pos` argument of `TextWriter.fillTextbox()` to indent the first line, so its text may continue any preceding one in a continuous manner.

6. MuPDF does not support all fonts with this feature, e.g. no Type3 fonts. Starting with v1.18.0 this can be checked via the font attribute `Font.isWritable`.

---

### 6.20 Tools

This class is a collection of utility methods and attributes, mainly around memory management. To simplify and speed up its use, it is automatically instantiated under the name `TOOLS` when PyMuPDF is imported.
<table>
<thead>
<tr>
<th>Method / Attribute</th>

</tbody>
</table>

### Class API

```python

class Tools

gen_id()

A convenience method returning a unique positive integer which will increase by 1 on every invocation. Example usages include creating unique keys in databases - its creation should be faster than using timestamps by an order of magnitude.

**Note:** MuPDF has dropped support for this in v1.14.0, so we have re-implemented a similar function with the following differences:

- It is not part of MuPDF’s global context and not threadsafe (not an issue because we do not support threads in PyMuPDF anyway).
- It is implemented as `int`. This means that the maximum number is `sys.maxsize`. Should this number ever be exceeded, the counter starts over again at 1.

**Return type:** int

**Returns:** a unique positive integer.
```

```python

set_annot_stem(stem=None)

(New in v1.18.6)
```

Set or inquire the prefix for the id of new annotations, fields or links.

**Parameters** `stem` (str) – if omitted, the current value is returned, default is “fitz”. Annotations, fields / widgets and links technically are subtypes of the same type of object (`/Annot`) in PDF documents. An `/Annot` object may be given a unique identifier within a page. For each of the applicable subtypes, PyMuPDF generates identifiers “stem-Annn”, “stem-Wnnn” or “stem-Lnnn” respectively. The number “nnn” is used to enforce the required uniqueness.

---

1 This memory area is internally used by MuPDF, and it serves as a cache for objects that have already been read and interpreted, thus improving performance. The most bulky object types are images and also fonts. When an application starts up the MuPDF library (in our case this happens as part of `import fitz`), it must specify a maximum size for this area. PyMuPDF’s uses the default value (256 MB) to limit memory consumption. Use the methods here to control or investigate store usage. For example: even after a document has been closed and all related objects have been deleted, the store usage may still not drop down to zero. So you might want to enforce that before opening another document.
**Return type**  str

Returns the current value.

`set_small_glyph_heights(on=None)`  
(New in v1.18.5)

Set or inquire reduced bbox heights in text extract and text search methods.

**Parameters**  
`on` *(bool)* – if omitted, the current setting is returned. For other values the `bool()` function is applied to set a global variable. If `True`, `Page.search_for()` and `Page.get_text()` methods return character, span, line or block bboxes that have a height of font size. If `False` (the standard setting when PyMuPDF is imported), bbox height will normally equal line height.

**Return type**  bool

Returns `True` or `False`.

`image_profile(stream)`  
(New in v1.16.17) Show important properties of an image provided as a memory area. Its main purpose is to avoid using other Python packages just to determine basic properties.

**Parameters**  
`stream` *(bytes, bytearray)* – the image data.

**Return type**  dict

Returns a dictionary with the keys “width”, “height”, “xres”, “yres”, “colorspace” (the `colorspace.n` value, number of colorants), “cs-name” (the `colorspace.name` value), “bpc”, “ext” (image type as file extension). The values for these keys are the same as returned by `Document.extract_image()`. Please also have a look at resolution.

**Note:**

- For some “exotic” images (FAX encodings, RAW formats and the like), this method will not work and return `None`. You can however still work with such images in PyMuPDF, e.g. by using `Document.extract_image()` or create pixmaps via `Pixmap(doc, xref)`. These methods will automatically convert exotic images to the PNG format before returning results.

- Some examples:

```
In [1]: import fitz
In [2]: stream = open(<image.file>, "rb").read()
In [3]: fitz.TOOLS.image_profile(stream)
Out[3]:
{ 'width': 439, 'height': 501, 'xres': 96, 'yres': 96, 'colorspace': 3, 'bpc': 8, 'ext': 'jpeg', 'cs-name': 'DeviceRGB'}
In [4]: doc=fitz.open(<input.pdf>)
In [5]: stream = doc.xref_stream_raw(5)  # no decompression!
In [6]: fitz.TOOLS.image_profile(stream)
Out[6]:
{ 'width': 816, 'height': 1056, 'xres': 96,}
```
store_shrink (percent)
Reduce the storables cache by a percentage of its current size.

Parameters percent (int) – the percentage of current size to free. If 100+ the store will be emptied, if zero, nothing will happen. MuPDF’s caching strategy is “least recently used”, so low-usage elements get deleted first.

Return type int
Returns the new current store size. Depending on the situation, the size reduction may be larger than the requested percentage.

show_aa_level ()
(New in version 1.16.14) Return the current anti-aliasing values. These values control the rendering quality of graphics and text elements.

Return type dict
Returns a dictionary with the following initial content: {'graphics': 8, 'text': 8, 'graphics_min_line_width': 0.0}.

set_aa_level (level)
(New in version 1.16.14) Set the new number of bits to use for anti-aliasing. The same value is taken currently for graphics and text rendering. This might change in a future MuPDF release.

Parameters level (int) – an integer ranging between 0 and 8. Value outside this range will be silently changed to valid values. The value will remain in effect throughout the current session or until changed again.

reset_mupdf_warnings ()
(New in version 1.16.0)
Empty MuPDF warnings message buffer.

mupdf_display_errors (value=None)
(New in version 1.16.8)
Show or set whether MuPDF errors should be displayed.

Parameters value (bool) – if not a bool, the current setting is returned. If true, MuPDF errors will be shown on sys.stderr, otherwise suppressed. In any case, messages continue to be stored in the warnings store. Upon import of PyMuPDF this value is True.

Returns True or False

mupdf_warnings (reset=True)
(New in version 1.16.0)
Return all stored MuPDF messages as a string with interspersed line-breaks.

Parameters reset (bool) – (new in version 1.16.7) whether to automatically empty the store.
fitz_config

A dictionary containing the actual values used for configuring PyMuPDF and MuPDF. Also refer to the installation chapter. This is an overview of the keys, each of which describes the status of a support aspect.

'tofu': False,
```

² Optionally, all dynamic management of memory can be done using Python C-level calls. MuPDF offers a hook to insert user-preferred memory managers. We are using option this for Python version 3 since PyMuPDF v1.13.19. At the same time, all memory allocation in PyMuPDF itself is also routed to Python (i.e. no more direct malloc() calls in the code). We have seen improved memory usage and slightly reduced runtimes with this option set. If you want to change this, you can set `#define JM_MEMORY 0` (uses standard C malloc, or 1 for Python allocation) in file `fitz.i` and then generate PyMuPDF.
{'tofu-cjk': True,
'tofu-cjk-ext': False,
'tofu-cjk-lang': False,
'tofu-emoji': False,
'tofu-historic': False,
'tofu-symbol': False,
'tofu-sil': False,
'icc': True,
'py-memory': True, # (False if Python 2)
'base14': True}

Return type dict

store_maxsize
Maximum storables cache size in bytes. PyMuPDF is generated with a value of 268'435'456 (256 MB, the default value), which you should therefore always see here. If this value is zero, then an “unlimited” growth is permitted.

Return type int

store_size
Current storables cache size in bytes. This value may change (and will usually increase) with every use of a PyMuPDF function. It will (automatically) decrease only when Tools.store_maxsize is going to be exceeded: in this case, MuPDF will evict low-usage objects until the value is again in range.

Return type int

6.20.1 Example Session

::

>>> import fitz
# print the maximum and current cache sizes
>>> fitz.TOOLS.store_maxsize
268435456
>>> fitz.TOOLS.store_size
0
>>> doc = fitz.open("demo1.pdf")
# pixmap creation puts lots of object in cache (text, images, fonts),
# apart from the pixmap itself
>>> pix = doc[0].get_pixmap(alpha=False)
>>> fitz.TOOLS.store_size
454519
# release (at least) 50% of the storage
>>> fitz.TOOLS.store_shrink(50)
13471
>>> fitz.TOOLS.store_size
13471
# get a few unique numbers
>>> fitz.TOOLS.gen_id()
1
>>> fitz.TOOLS.gen_id()
2
>>> fitz.TOOLS.gen_id()
3

(continues on next page)
# close document and see how much cache is still in use
>>> doc.close()
>>> fitz.TOOLS.store_size
0

6.21 Widget

This class represents a PDF Form field, also called a “widget”. Throughout this documentation, we are using these terms synonymously. Fields technically are a special case of PDF annotations, which allow users with limited permissions to enter information in a PDF. This is primarily used for filling out forms.

Like annotations, widgets live on PDF pages. Similar to annotations, the first widget on a page is accessible via Page.firstWidget and subsequent widgets can be accessed via the Widget.next property.

(Changed in version 1.16.0) MuPDF no longer treats widgets as a subset of general annotations. Consequently, Page.firstAnnot and Annot.next() will deliver non-widget annotations exclusively, and be None if only form fields exist on a page. Vice versa, Page.firstWidget and Widget.next() will only show widgets. This design decision is purely internal to MuPDF; technically, links, annotations and fields have a lot in common and also continue to share the better part of their code within (Py-) MuPDF.

Class API

class Widget

    update()
    After any changes to a widget, this method **must be used** to store them in the PDF\(^1\).

    reset()
    Reset the field’s value to its default – if defined – or remove it. Do not forget to issue update() afterwards.

    next
    Point to the next form field on the page. The last widget returns None.

    border_color
    A list of up to 4 floats defining the field’s border color. Default value is None which causes border style and border width to be ignored.

    border_style
    A string defining the line style of the field’s border. See Annot.border. Default is “s” (“Solid”) – a continuous line. Only the first character (upper or lower case) will be regarded when creating a widget.

    border_width
    A float defining the width of the border line. Default is 1.

    border_dashes
    A list/tuple of integers defining the dash properties of the border line. This is only meaningful if border_style == “D” and border_color is provided.

    choice_values
    Python sequence of strings defining the valid choices of list boxes and combo boxes. For these widget types, this property is mandatory and must contain at least two items. Ignored for other types.

---

\(^{1}\) If you intend to re-access a new or updated field (e.g. for making a pixmap), make sure to reload the page first. Either close and re-open the document, or load another page first, or simply do page = doc.reload_page(page).
field_name
A mandatory string defining the field’s name. No checking for duplicates takes place.

field_label
An optional string containing an “alternate” field name. Typically used for any notes, help on field usage, etc. Default is the field name.

field_value
The value of the field.

field_flags
An integer defining a large amount of properties of a field. Be careful when changing this attribute as this may change the field type.

field_type
A mandatory integer defining the field type. This is a value in the range of 0 to 6. It cannot be changed when updating the widget.

field_type_string
A string describing (and derived from) the field type.

fill_color
A list of up to 4 floats defining the field’s background color.

button_caption
The caption string of a button-type field.

is_signed
A bool indicating the signing status of a signature field, else None.

rect
The rectangle containing the field.

text_color
A list of 1, 3 or 4 floats defining the text color. Default value is black \([0, 0, 0]\).

text_font
A string defining the font to be used. Default and replacement for invalid values is “Helv”. For valid font reference names see the table below.

text_fontsize
A float defining the text fontsize. Default value is zero, which causes PDF viewer software to dynamically choose a size suitable for the annotation’s rectangle and text amount.

text_maxlen
An integer defining the maximum number of text characters. PDF viewers will (should) not accept a longer text.

text_type
An integer defining acceptable text types (e.g. numeric, date, time, etc.). For reference only for the time being – will be ignored when creating or updating widgets.

xref
The PDF xref of the widget.

script
(New in version 1.16.12) JavaScript text (unicode) for an action associated with the widget, or None. This is the only script action supported for button type widgets.

script_stroke
(New in version 1.16.12) JavaScript text (unicode) to be performed when the user types a key-stroke into
a text field or combo box or modifies the selection in a scrollable list box. This action can check the keystroke for validity and reject or modify it. *None* if not present.

**script_format**

*(New in version 1.16.12)* JavaScript text (unicode) to be performed before the field is formatted to display its current value. This action can modify the field’s value before formatting. *None* if not present.

**script_change**

*(New in version 1.16.12)* JavaScript text (unicode) to be performed when the field’s value is changed. This action can check the new value for validity. *None* if not present.

**script_calc**

*(New in version 1.16.12)* JavaScript text (unicode) to be performed to recalculate the value of this field when that of another field changes. *None* if not present.

---

**Note:**

1. For *adding* or *changing* one of the above scripts, just put the appropriate JavaScript source code in the widget attribute. To *remove* a script, set the respective attribute to *None*.

2. Button fields only support *script*. Other script entries will automatically be set to *None*.

---

### 6.21.1 Standard Fonts for Widgets

Widgets use their own resources object `/DR`. A widget resources object must at least contain a `/Font` object. Widget fonts are independent from page fonts. We currently support the 14 PDF base fonts using the following fixed reference names, or any name of an already existing field font. When specifying a text font for new or changed widgets, *either* choose one in the first table column (upper and lower case supported), *or* one of the already existing form fonts. In the latter case, spelling must exactly match.

To find out already existing field fonts, inspect the list `Document.FormFonts`.

<table>
<thead>
<tr>
<th>Reference</th>
<th>Base14 Fontname</th>
</tr>
</thead>
<tbody>
<tr>
<td>CoBI</td>
<td>Courier-BoldOblique</td>
</tr>
<tr>
<td>CoBo</td>
<td>Courier-Bold</td>
</tr>
<tr>
<td>CoIt</td>
<td>Courier-Oblique</td>
</tr>
<tr>
<td>Cour</td>
<td>Courier</td>
</tr>
<tr>
<td>HeBI</td>
<td>Helvetica-BoldOblique</td>
</tr>
<tr>
<td>HeBo</td>
<td>Helvetica-Bold</td>
</tr>
<tr>
<td>HeIt</td>
<td>Helvetica-Oblique</td>
</tr>
<tr>
<td>Helv</td>
<td>Helvetica <em>(default)</em></td>
</tr>
<tr>
<td>Symb</td>
<td>Symbol</td>
</tr>
<tr>
<td>TiBI</td>
<td>Times-BoldItalic</td>
</tr>
<tr>
<td>TiBo</td>
<td>Times-Bold</td>
</tr>
<tr>
<td>TiIt</td>
<td>Times-Italic</td>
</tr>
<tr>
<td>TiRo</td>
<td>Times-Roman</td>
</tr>
<tr>
<td>ZaDb</td>
<td>ZapfDingbats</td>
</tr>
</tbody>
</table>

You are generally free to use any font for every widget. However, we recommend using *ZaDb* (“ZapfDingbats”) and fontsize 0 for check boxes: typical viewers will put a correctly sized tickmark in the field’s rectangle, when it is clicked.
6.21.2 Supported Widget Types

PyMuPDF supports the creation and update of many, but not all widget types.

- text (PDF_WIDGET_TYPE_TEXT)
- push button (PDF_WIDGET_TYPE_BUTTON)
- check box (PDF_WIDGET_TYPE_CHECKBOX)
- combo box (PDF_WIDGET_TYPE_COMBOBOX)
- list box (PDF_WIDGET_TYPE_LISTBOX)
- radio button (PDF_WIDGET_TYPE_RADIOBUTTON): PyMuPDF does not currently support groups of (interconnected) buttons, where setting one automatically unsets the other buttons in the group. The widget object also does not reflect the presence of a button group. Setting or unsetting happens via values True and False and will always work without affecting other radio buttons.
- signature (PDF_WIDGET_TYPE_SIGNATURE) read only.
Operator Algebra for Geometry Objects

Instances of classes `Point`, `IRect`, `Rect` and `Matrix` are collectively also called “geometry” objects. They all are special cases of Python sequences, see *Using Python Sequences as Arguments in PyMuPDF* for more background.

We have defined operators for these classes that allow dealing with them (almost) like ordinary numbers in terms of addition, subtraction, multiplication, division, and some others.

This chapter is a synopsis of what is possible.

### 7.1 General Remarks

1. Operators can be either **binary** (i.e. involving two objects) or **unary**.
2. The resulting type of **binary** operations is either a **new object of the left operand’s class** or a bool.
3. The result of **unary** operations is either a **new object** of the same class, a bool or a float.
4. The binary operators `+`, `-`, `*`, `/` are defined for all classes. They *roughly* do what you would expect – except, that the second operand . . .
   - may always be a number which then performs the operation on every component of the first one,
   - may always be a numeric sequence of the same length (2, 4 or 6) – we call such sequences **point_like**, `rect_like` or `matrix_like`, respectively.
5. Rectangles support additional binary operations: **intersection** (operator “&”), **union** (operator “|”) and **containment** checking.
6. Binary operators fully support in-place operations, so expressions like “a /= b” are valid if b is numeric or “a_like”.
7.2 Unary Operations

<table>
<thead>
<tr>
<th>Oper.</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool(OBJ)</td>
<td>is false exactly if all components of OBJ are zero</td>
</tr>
<tr>
<td>abs(OBJ)</td>
<td>the rectangle area – equal to norm(OBJ) for the other types</td>
</tr>
<tr>
<td>norm(OBJ)</td>
<td>square root of the component squares (Euclidean norm)</td>
</tr>
<tr>
<td>+OBJ</td>
<td>new copy of OBJ</td>
</tr>
<tr>
<td>-OBJ</td>
<td>new copy of OBJ with negated components</td>
</tr>
<tr>
<td>~m</td>
<td>inverse of matrix “m”, or the null matrix if not invertible</td>
</tr>
</tbody>
</table>

7.3 Binary Operations

For every geometry object “a” and every number “b”, the operations “a ° b” and “a °= b” are always defined for the operators +, -, *, /. The respective operation is simply executed for each component of “a”. If the second operand is not a number, then the following is defined:

<table>
<thead>
<tr>
<th>Oper.</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>a+b, a-b</td>
<td>component-wise execution, “b” must be “a-like”.</td>
</tr>
<tr>
<td>a*m, a/m</td>
<td>“a” can be a point, rectangle or matrix, but “m” must be matrix_like. “a/m” is treated as “a~m” (see note below for non-invertible matrices). If “a” is a point or a rectangle, then “a.transform(m)” is executed. If “a” is a matrix, then matrix concatenation takes place.</td>
</tr>
<tr>
<td>a&amp;b</td>
<td>intersection rectangle: “a” must be a rectangle and “b” rect_like. Delivers the largest rectangle contained in both operands.</td>
</tr>
<tr>
<td>alb</td>
<td>union rectangle: “a” must be a rectangle, and “b” may be point_like or rect_like. Delivers the smallest rectangle containing both operands.</td>
</tr>
<tr>
<td>b in a</td>
<td>if “b” is a number, then “b in tuple(a)” is returned. If “b” is point_like or rect_like, then “a” must be a rectangle, and “a.contains(b)” is returned.</td>
</tr>
<tr>
<td>a == b</td>
<td>True if bool(a-b) is False (“b” may be “a-like”).</td>
</tr>
</tbody>
</table>

Note: Please note an important difference to usual arithmetics:

Matrix multiplication is not commutative, i.e. in general we have m*n != n*m for two matrices. Also, there are non-zero matrices which have no inverse, for example m = Matrix(1, 0, 1, 0, 1, 0). If you try to divide by any of these you will receive a ZeroDivisionError exception using operator “/”, e.g. for fitz.Identity / m. But if you formulate fitz.Identity * ~m, the result will be fitz.Matrix() (the null matrix).

Admittedly, this represents an inconsistency, and we are considering to remove it. For the time being, you can choose to avoid an exception and check whether ~m is the null matrix, or accept a potential ZeroDivisionError by using fitz.Identity / m.
7.4 Some Examples

7.4.1 Manipulation with numbers

For the usual arithmetic operations, numbers are always allowed as second operand. In addition, you can formulate “x in OBJ”, where x is a number. It is implemented as “x in tuple(OBJ)”: 

```python
>>> fitz.Rect(1, 2, 3, 4) + 5
fitz.Rect(6.0, 7.0, 8.0, 9.0)
>>> 3 in fitz.Rect(1, 2, 3, 4)
True
```

The following will create the upper left quarter of a document page rectangle:

```python
>>> page.rect
Rect(0.0, 0.0, 595.0, 842.0)
>>> page.rect / 2
Rect(0.0, 0.0, 297.5, 421.0)
```

The following will deliver the middle point of a line connecting two points p1 and p2:

```python
>>> p1 = fitz.Point(1, 2)
>>> p2 = fitz.Point(4711, 3141)
>>> mp = (p1 + p2) / 2
>>> mp
Point(2356.0, 1571.5)
```

7.4.2 Manipulation with “like” Objects

The second operand of a binary operation can always be “like” the left operand. “Like” in this context means “a sequence of numbers of the same length”. With the above examples:

```python
>>> p1 + p2
Point(4712.0, 3143.0)
>>> p1 + (4711, 3141)
Point(4712.0, 3143.0)
>>> p1 += (4711, 3141)
>>> p1
Point(4712.0, 3143.0)
```

To shift a rectangle for 5 pixels to the right, do this:

```python
>>> fitz.Rect(100, 100, 200, 200) + (5, 0, 5, 0)  # add 5 to the x coordinates
Rect(105.0, 100.0, 205.0, 200.0)
```

Points, rectangles and matrices can be transformed with matrices. In PyMuPDF, we treat this like a “multiplication” (or resp. “division”), where the second operand may be “like” a matrix. Division in this context means “multiplication with the inverted matrix”: 

```python
```
As a specialty, rectangles support additional binary operations:

- **intersection** – the common area of rectangle-likes, operator “&”
- **inclusion** – enlarge to include a point-like or rect-like, operator “|”
- **containment** check – whether a point-like or rect-like is inside

Here is an example for creating the smallest rectangle enclosing given points:
Rect(0.0, 0.0, 9.0, 9.0)

```python
>>> (4, 5) in r  # this point-like lies inside the rectangle
True
>>> # and this rect-like is also inside
>>> (4, 4, 5, 5) in r
True
>>>```

7.4. Some Examples
Low Level Functions and Classes

Contains a number of functions and classes for the experienced user. To be used for special needs or performance requirements.

8.1 Functions

The following are miscellaneous functions and attributes on a fairly low-level technical detail.

Some functions provide detail access to PDF structures. Others are stripped-down, high performance versions of other functions which provide more information.

Yet others are handy, general-purpose utilities.

<table>
<thead>
<tr>
<th>Function</th>
<th>Short Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Annot.clean_contents()</td>
<td>PDF only: clean the annot’s contents object</td>

</table>

**PaperSize (s)**

Convenience function to return width and height of a known paper format code. These values are given in pixels for the standard resolution 72 pixels = 1 inch.

A format name must be supplied as a string (case **s**ensitive), optionally suffixed with ‘-L’ (landscape) or ‘-P’ (portrait). No suffix defaults to portrait.

**Parameters** s (str) – any format name from above (upper or lower case), like “A4” or “letter-l”.

**Return type** tuple

**Returns** (width, height) of the paper format. For an unknown format (-1, -1) is returned.

**PaperRect (s)**

Convenience function to return a `Rect` for a known paper format.

**Parameters** s (str) – any format name supported by `PaperSize()`.

**Return type** `Rect`
Returns :meth:`fitz.Rect(0, 0, width, height)` with width, height=fitz.PaperSize(s).

```python
>>> import fitz

>>> fitz.PaperRect("letter-l")
fitz.Rect(0.0, 0.0, 792.0, 612.0)
```
adobe_glyph_unicharcs()  
*New in v1.18.0*

Return a list of unicodes for there exists a glyph name in the Adobe Glyph List.

**Return type** list

**Returns** list of integers.

**Note:** A similar functionality is provided by package fontTools in its agl sub-package.

sRGB_to_rgb(srgb)  
*New in v1.17.4*

Convenience function returning a color (red, green, blue) for a given sRGB color integer.

**Parameters**

- **srgb** (*int*) – an integer of format RRGGBB, where each color component is an integer in range(255).

**Returns** a tuple (red, green, blue) with integer items in intervall \(0 <= \text{item} <= 255\) representing the same color.

make_table(rect, cols=1, rows=1)  
*New in v1.17.4*

Convenience function to split a rectangle into sub-rectangles. Returns a list of rows lists, each containing cols Rect items. Each sub-rectangle can then be addressed by its row and column index.

**Parameters**

- **rect** (*rect_like*) – the rectangle to split.
- **cols** (*int*) – the desired number of columns.
- **rows** (*int*) – the desired number of rows.

**Returns** a list of Rect objects of equal size, whose union equals rect. Here is the layout of a 3x4 table created by `cell = fitz.make_table(rect, cols=4, rows=3)`:

<table>
<thead>
<tr>
<th>cell[0][0]</th>
<th>cell[0][1]</th>
<th>cell[0][2]</th>
<th>cell[0][3]</th>
</tr>
</thead>
<tbody>
<tr>
<td>cell[1][0]</td>
<td>cell[1][1]</td>
<td>cell[1][2]</td>
<td>cell[1][3]</td>
</tr>
</tbody>
</table>
**planishLine** (*p1, p2*)

*(New in version 1.16.2)*

Return a matrix which maps the line from *p1* to *p2* to the x-axis such that *p1* will become (0,0) and *p2* a point with the same distance to (0,0).

**Parameters**

- **p1** (**point_like**) – starting point of the line.
- **p2** (**point_like**) – end point of the line.

**Return type** *Matrix*

**Returns**

A matrix which combines a rotation and a translation:

```python
p1 = fitz.Point(1, 1)
p2 = fitz.Point(4, 5)
abs(p2 - p1)  # distance of points
5.0
m = fitz.planishLine(p1, p2)
p1 * m
Point(0.0, 0.0)
p2 * m
Point(5.0, -5.960464477539063e-08)
# distance of the resulting points
abs(p2 * m - p1 * m)
5.0
```

---

**paperSizes**

A dictionary of pre-defines paper formats. Used as basis for *PaperSize()*.

---

**fitz_fontdescriptors**

*(New in v1.17.5)*

A dictionary of usable fonts from repository *pymupdf-fonts*. Items are keyed by their reserved fontname and provide information like this:

```python
In [2]: fitz.fitz_fontdescriptors.keys()
Out[2]: dict_keys(['figbo', 'figo', 'figbi', 'figit', 'fimbo', 'fimo', 'spacembo', 'spacembi', 'spacemit', 'spacemo', 'math', 'music', 'symbol1 ─', ...
```

(continues on next page)
In [3]: fitz.fitz_fontdescriptors['fimo']
Out[3]:
{'name': 'Fira Mono Regular', 'size': 125712, 'mono': True, 'bold': False, 'italic': False, 'serif': True, 'glyphs': 1485}

getPDFnow()

Convenience function to return the current local timestamp in PDF compatible format, e.g. D:20170501121525-04'00' for local datetime May 1, 2017, 12:15:25 in a timezone 4 hours westward of the UTC meridian.

Return type  str

Returns  current local PDF timestamp.

getTextlength (text, fontname="helv", fontsize=11, encoding=TEXT_ENCODING_LATIN)

(New in version 1.14.7)

Calculate the length of text on output with a given built-in font, fontsize and encoding.

Parameters

- text (str) – the text string.
- fontname (str) – the fontname. Must be one of either the PDF Base 14 Fonts or the CJK fonts, identified by their “reserved” fontnames (see table in :meth:`Page.insertFont`).
- fontsize (float) – size of the font.
- encoding (int) – the encoding to use. Besides 0 = Latin, 1 = Greek and 2 = Cyrillic (Russian) are available. Relevant for Base-14 fonts “Helvetica”, “Courier” and “Times” and their variants only. Make sure to use the same value as in the corresponding text insertion.

Return type  float

Returns  the length in points the string will have (e.g. when used in :meth:`Page.insertText()`).

Note:  This function will only do the calculation – it won’t insert font or text.

Warning:  If you use this function to determine the required rectangle width for the (:meth:`Page` or :meth:`Shape`) :meth:`insertTextbox` methods, be aware that they calculate on a by-character level. Because of rounding effects, this will mostly lead to a slightly larger number: \( \sum\{\text{fitz.getTextlength(c)} \text{ for c in text}\} > \text{fitz.getTextlength(text)} \). So either (1) do the same, or (2) use something like \( \text{fitz.getTextlength(text + "'"')} \) for your calculation.
**getPDFstr** *(text)*

Make a PDF-compatible string: if the text contains code points \( \text{ord}(c) > 255 \), then it will be converted to UTF-16BE with BOM as a hexadecimal character string enclosed in “<>” brackets like `<feff...>`. Otherwise, it will return the string enclosed in (round) brackets, replacing any characters outside the ASCII range with some special code. Also, every “(“, “)” or backslash is escaped with an additional backslash.

**Parameters**
- `text` *(str)* – the object to convert

**Return type** *str*

**Returns**
PDF-compatible string enclosed in either () or <>.

**ImageProperties** *(stream)*

*(New in version 1.14.14)*

Return a number of basic properties for an image.

**Parameters**
- `stream` *(bytes|bytearray|BytesIO|file)* – an image either in memory or an opened file. A memory resident image maybe any of the formats bytes, bytearray or io.BytesIO.

**Returns**

a dictionary with the following keys (an empty dictionary for any error):

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>(int) width in pixels</td>
</tr>
<tr>
<td>height</td>
<td>(int) height in pixels</td>
</tr>
<tr>
<td>colorspace</td>
<td>(int) colorspace.n (e.g. 3 = RGB)</td>
</tr>
<tr>
<td>bpc</td>
<td>(int) bits per component (usually 8)</td>
</tr>
<tr>
<td>format</td>
<td>(int) image format in range(15)</td>
</tr>
<tr>
<td>ext</td>
<td>(str) image file extension indicating the format</td>
</tr>
<tr>
<td>size</td>
<td>(int) length of the image in bytes</td>
</tr>
</tbody>
</table>

**Example:**

```python
>>> fitz.ImageProperties(open("img-clip.jpg","rb"))
{'bpc': 8, 'format': 9, 'colorspace': 3, 'height': 325, 'width': 244, 'ext': 'jpeg', 'size': 14161}
```

**ConversionHeader** *("text", filename="UNKNOWN")*

Return the header string required to make a valid document out of page text outputs.

**Parameters**
- `output` *(str)* – type of document. Use the same as the output parameter of `get_text()`.
- `filename` *(str)* – optional arbitrary name to use in output types “json” and “xml”.

**Return type** *str*
**ConversionTrailer** *(output)*

Return the trailer string required to make a valid document out of page text outputs. See *Page*.
*get_text()* for an example.

**Parameters**

- **output** *(str)* – type of document. Use the same as the output parameter of *get_text()*.

**Return type** str

---

**Document**.delete_object *(xref)*

PDF only: Delete an object given by its cross reference number.

**Parameters**

- **xref** *(int)* – the cross reference number. Must be within the document’s valid xref range.

**Warning:** Only use with extreme care: this may make the PDF unreadable.

---

**Document**.del_xml_metadata()

Delete an object containing XML-based metadata from the PDF. (Py-) MuPDF does not support XML-based metadata. Use this if you want to make sure that the conventional metadata dictionary will be used exclusively. Many thirdparty PDF programs insert their own metadata in XML format and thus may override what you store in the conventional dictionary. This method deletes any such reference, and the corresponding PDF object will be deleted during next garbage collection of the file.

---

**Document**.xml_metadata_xref()

Return the XML-based metadata xref of the PDF if present – also refer to *Document*._delXmlMetadata(). You can use it to retrieve the content via *Document*.xrefStream() and then work with it using some XML software.

**Return type** int

**Returns** xref of PDF file level XML metadata – or 0 if none exists.

---

**Page**.run *(dev, transform)*

Run a page through a device.

**Parameters**

- **dev** *(Device)* – Device, obtained from one of the *Device* constructors.
- **transform** *(Matrix)* – Transformation to apply to the page. Set it to *Identity* if no transformation is desired.

---

**Page**.wrap_contents()

Put string pair “q” / “Q” before, resp. after a page’s /Contents object(s) to ensure that any “geometry” changes are local only.

Use this method as an alternative, minimalistic version of *Page*.clean_contents(). Its advantage is a small footprint in terms of processing time and impact on the data size of incremental saves.

---

Chapter 8. Low Level Functions and Classes
**Page.is_wrapped**

Indicate whether `Page.wrap_contents()` may be required for object insertions in standard PDF geometry. Please note that this is a quick, basic check only: a value of `False` may still be a false alarm.

**Page.get_text_blocks** *(flags=None)*

Deprecated wrapper for `TextPage.extractBLOCKS()`. Use `Page.getText()` with the “blocks” option instead.

**Page.get_text_words** *(flags=None)*

Deprecated wrapper for `TextPage.extractWORDS()`. Use `Page.getText()` with the “words” option instead.

**Page.get_displaylist**

Run a page through a list device and return its display list.

**Return type** *DisplayList*

**Returns** the display list of the page.

**Page.get_contents**

PDF only: Retrieve a list of `xref` of `contents` objects of a page. May be empty or contain multiple integers. If the page is cleaned (`Page.clean_contents()`), it will be one entry at most. The “source” of each `/Contents` object can be individually read by `Document.xref_stream()` using an item of this list. Method `Page.read_contents()` in contrast walks through this list and concatenates the corresponding sources into one `bytes` object.

**Page.clean_contents** *(sanitize=True)*

(Changed in v1.17.6)

PDF only: Clean and concatenate all `contents` objects associated with this page. “Cleaning” includes syntactical corrections, standardizations and “pretty printing” of the contents stream. Discrepancies between `contents` and `resources` objects will also be corrected if `sanitize` is true. See `Page.get_contents()` for more details.

Changed in version 1.16.0 Annotations are no longer implicitly cleaned by this method. Use `Annot._cleanContents()` separately.

**Parameters**

- **sanitize** *(bool)* – *(new in v1.17.6)* if true, synchronization between resources and their actual use in the contents object is synchronized. For example, if a font is not actually used for any text of the page, then it will be deleted from the `/Resources/Font` object.

**Warning:** This is a complex function which may generate large amounts of new data and render old data unused. It is **not recommended** using it together with the **incremental save** option. Also note that the resulting singleton new `/Contents` object is **uncompressed**. So you should save to a **new file** using options “`deflate=True, garbage=3`”.

8.1. Functions 255
**Page.read_contents()**

New in version 1.17.0. Return the concatenation of all contents objects associated with the page – without cleaning or otherwise modifying them. Use this method whenever you need to parse this source in its entirety without having to bother how many separate contents objects exist.

**Annot.clean_contents(sanitize=True)**

Clean the contents streams associated with the annotation. This is the same type of action which Page.clean_contents() performs – just restricted to this annotation.

**Document.get_char_widths(xref=0, limit=256)**

Return a list of character glyphs and their widths for a font that is present in the document. A font must be specified by its PDF cross reference number xref. This function is called automatically from Page.insertText() and Page.insertTextbox(). So you should rarely need to do this yourself.

Parameters

- **xref (int)** – cross reference number of a font embedded in the PDF. To find a font xref, use e.g. doc.get_page_fonts(pno) of page number pno and take the first entry of one of the returned list entries.
- **limit (int)** – limits the number of returned entries. The default of 256 is enforced for all fonts that only support 1-byte characters, so-called “simple fonts” (checked by this method). All PDF Base 14 Fonts are simple fonts.

Return type  list

Returns a list of limit tuples. Each character c has an entry (g, w) in this list with an index of ord(c). Entry g (integer) of the tuple is the glyph id of the character, and float w is its normalized width. The actual width for some fontsize can be calculated as w * fontsize. For simple fonts, the g entry can always be safely ignored. In all other cases g is the basis for graphically representing c.

This function calculates the pixel width of a string called text:

```python
def pixlen(text, widthlist, fontsize):
    try:
        return sum([widthlist[ord(c)] for c in text]) * fontsize
    except IndexError:
        m = max([ord(c) for c in text])
        raise ValueError("max. code point found: \%i, increase limit" % m)
```

**Document.is_stream(xref)**

(New in version 1.14.14)

PDF only: Check whether the object represented by xref is a stream type. Return is False if not a PDF or if the number is outside the valid xref range.

Parameters **xref (int)** – xref number.

Returns True if the object definition is followed by data wrapped in keyword pair stream, endstream.
Document `get_new_xref()`

Increase the `xref` by one entry and return that number. This can then be used to insert a new object.

**Return type** int

**Returns** the number of the new `xref` entry.

Document `xref_length()`

Return length of `xref` table.

**Return type** int

**Returns** the number of entries in the `xref` table.

Document `extract_image(xref)`

PDF Only: Extract data and meta information of an image stored in the document. The output can directly be used to be stored as an image file, as input for PIL, Pixmap creation, etc. This method avoids using pixmaps wherever possible to present the image in its original format (e.g. as JPEG).

**Parameters**

- `xref` (int) – `xref` of an image object. If this is not in `range(1, doc.xref_length())`, or the object is no image or other errors occur, `None` is returned and no exception is raised.

**Return type** dict

**Returns**

A dictionary with the following keys:

- `ext` (str) image type (e.g. 'jpeg'), usable as image file extension
- `smask` (int) `xref` number of a stencil (/SMask) image or zero
- `width` (int) image width
- `height` (int) image height
- `colorspace` (int) the image’s `colorspace.n` number.
- `cs-name` (str) the image’s `colorspace.name`.
- `xres` (int) resolution in x direction. Please also see resolution.
- `yres` (int) resolution in y direction. Please also see resolution.
- `image` (bytes) image data, usable as image file content

```python
d = doc.extract_image(1373)
d
{'ext': 'png', 'smask': 2934, 'width': 5, 'height': 629, 'colorspace': 3, 'xres': 96, 'yres': 96, 'cs-name': 'DeviceRGB', 'image': b'\x89PNG\r
\xd8\x1a\n\x00\x00\x00\rIHDR\x00\x00\x00\x08\xc6\x00\x06\x00\x05 ...'}
imgout = open("image." + d["ext"], "wb")
imgout.write(d["image"])
102
imgout.close()
```
Note: There is a functional overlap with pix = fitz.Pixmap(doc, xref), followed by a pix.getPNGData(). Main differences are that extract_image, (1) does not always deliver PNG image formats, (2) is very much faster with non-PNG images, (3) usually results in much less disk storage for extracted images, (4) returns None in error cases (generates no exception). Look at the following example images within the same PDF.

- xref 1268 is a PNG – Comparable execution time and identical output:

  In [23]: %timeit pix = fitz.Pixmap(doc, 1268);pix.getPNGData()
  10.8 ms ± 52.4 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)
  In [24]: len(pix.getPNGData())
  Out[24]: 21462

  In [25]: %timeit img = doc.extract_image(1268)
  10.8 ms ± 86 µs per loop (mean ± std. dev. of 7 runs, 100 loops each)
  In [26]: len(img["image"])
  Out[26]: 21462

- xref 1186 is a JPEG – Document.extract_image() is many times faster and produces a much smaller output (2.48 MB vs. 0.35 MB):

  In [27]: %timeit pix = fitz.Pixmap(doc, 1186);pix.getPNGData()
  341 ms ± 2.86 ms per loop (mean ± std. dev. of 7 runs, 1 loop each)
  In [28]: len(pix.getPNGData())
  Out[28]: 2599433

  In [29]: %timeit img = doc.extract_image(1186)
  15.7 µs ± 116 ns per loop (mean ± std. dev. of 7 runs, 100000 loops each)
  In [30]: len(img["image"])
  Out[30]: 371177

Document.extract_font(xref, info_only=False)

PDF Only: Return an embedded font file’s data and appropriate file extension. This can be used to store the font as an external file. The method does not throw exceptions (other than via checking for PDF and valid xref).

Parameters

- xref (int) – PDF object number of the font to extract.

- info_only (bool) – only return font information, not the buffer. To be used for information-only purposes, avoids allocation of large buffer areas.

Returns

tuple

a tuple (basename, ext, subtype, buffer), where ext is a 3-byte suggested file extension (str), basename is the font’s name (str), subtype is the font’s type (e.g. “Type1”) and buffer is a bytes object containing the font file’s content (or b”””). For possible extension values and their meaning see Font File Extensions. Return details on error:

- ("", ",", ",", b""”) – invalid xref or xref is not a (valid) font object.
• (basename, “n/a”, “Type1”, b””) – basename is one of the PDF Base 14 Fonts, which cannot be extracted.

Example:

```python
>>> # store font as an external file
>>> name, ext, buffer = doc.extract_font(4711)
>>> # assuming buffer is not None:
>>> ofile = open(name + "." + ext, "wb")
>>> ofile.write(buffer)
>>> ofile.close()
```

**Warning:** The basename is returned unchanged from the PDF. So it may contain characters (such as blanks) which may disqualify it as a filename for your operating system. Take appropriate action.

Document.FontInfos

Contains following information for any font inserted via Page.insertFont() in this session of PyMuPDF:

- xref (int) – XREF number of the /Type/Font object.
- info (dict) – detail font information with the following keys:
  - name (str) – name of the basefont
  - idx (int) – index number for multi-font files
  - type (str) – font type (like “TrueType”, “Type0”, etc.)
  - ext (str) – extension to be used, when font is extracted to a file (see Font File Extensions).
  - glyphs (list) – list of glyph numbers and widths (filled by textinsertion methods).

Return type list

### 8.2 Device

The different format handlers (pdf, xps, etc.) interpret pages to a “device”. Devices are the basis for everything that can be done with a page: rendering, text extraction and searching. The device type is determined by the selected construction method.

**Class API**

```python
class Device

    __init__(self, object, clip)
    Constructor for either a pixel map or a display list device.

    Parameters

    • object (Pixmap or DisplayList) – either a Pixmap or a DisplayList.
```
• **clip (IRect)** – An optional IRect for Pixmap devices to restrict rendering to a certain area of the page. If the complete page is required, specify None. For display list devices, this parameter must be omitted.

```python
__init__(self, textpage, flags=0)
```
Constructor for a text page device.

**Parameters**

- **textpage (TextPage)** – TextPage object
- **flags (int)** – control the way how text is parsed into the text page. Currently 3 options can be coded into this parameter, see Preserve Text Flags. To set these options use something like flags=0 | TEXT_PRESERVE_LIGATURES | ....

### 8.3 Working together: DisplayList and TextPage

Here are some instructions on how to use these classes together.

In some situations, performance improvements may be achievable, when you fall back to the detail level explained here.

#### 8.3.1 Create a DisplayList

A DisplayList represents an interpreted document page. Methods for pixmap creation, text extraction and text search are – behind the curtain – all using the page’s display list to perform their tasks. If a page must be rendered several times (e.g. because of changed zoom levels), or if text search and text extraction should both be performed, overhead can be saved, if the display list is created only once and then used for all other tasks.

```python
>>> dl = page.getDisplayList()  # create the display list
```

You can also create display lists for many pages “on stack” (in a list), may be during document open, during idling times, or you store it when a page is visited for the first time (e.g. in GUI scripts).

Note, that for everything what follows, only the display list is needed – the corresponding Page object could have been deleted.

#### 8.3.2 Generate Pixmap

The following creates a Pixmap from a DisplayList. Parameters are the same as for Page.get_pixmap().

```python
>>> pix = dl.get_pixmap()  # create the page’s pixmap
```

The execution time of this statement may be up to 50% shorter than that of Page.getPixMap().

#### 8.3.3 Perform Text Search

With the display list from above, we can also search for text.

For this we need to create a TextPage.
>>> tp = dl.get_textpage()  # display list from above
>>> rlist = tp.search("needle")  # look up "needle" locations
>>> for r in rlist:
    # work with the found locations, e.g.
    pix.invertIRect(r.irect)  # invert colors in the rectangles

8.3.4 Extract Text

With the same TextPage object from above, we can now immediately use any or all of the 5 text extraction methods.

Note: Above, we have created our text page without argument. This leads to a default argument of 3 (ligatures and white-space are preserved), IAW images will not be extracted – see below.

>>> txt = tp.extractText()  # plain text format
>>> json = tp.extractJSON()  # json format
>>> html = tp.extractHTML()  # HTML format
>>> xml = tp.extractXML()  # XML format
>>> xml = tp.extractXHTML()  # XHTML format

8.3.5 Further Performance improvements

8.3.5.1 Pixmap

As explained in the Page chapter:

If you do not need transparency set alpha = 0 when creating pixmaps. This will save 25% memory (if RGB, the most common case) and possibly 5% execution time (depending on the GUI software).

8.3.5.2 TextPage

If you do not need images extracted alongside the text of a page, you can set the following option:

```python
>>> flags = fitz.TEXT_PRESERVE_LIGATURES | fitz.TEXT_PRESERVE_WHITESPACE
>>> tp = dl.get_textpage(flags)
```

This will save ca. 25% overall execution time for the HTML, XHTML and JSON text extractions and hugely reduce the amount of storage (both, memory and disk space) if the document is graphics oriented.

If you however do need images, use a value of 7 for flags:

```python
>>> flags = fitz.TEXT_PRESERVE_LIGATURES | fitz.TEXT_PRESERVE_WHITESPACE | fitz.TEXT_PRESERVE_IMAGES
```
matrix_like
A Python sequence of 6 numbers.

rect_like
A Python sequence of 4 numbers.

irect_like
A Python sequence of 4 integers.

point_like
A Python sequence of 2 numbers.

quad_like
A Python sequence of 4 point_like items.

inheritable
A number of values in a PDF can be specified once and then be inherited by objects further down in a parent-child relationship. The mediabox (physical size) of pages can for example be specified in some node(s) of the pagetree and will then be taken as value for all kids, which do not specify their own value.

MediaBox
A PDF array of 4 floats specifying a physical page size – (inheritable).

CropBox
A PDF array of 4 floats specifying a page’s visible area – (inheritable). This value is not affected if the page is rotated. In contrast to the page rectangle, Page.rect, the top-left corner of the cropbox may or may not be (0, 0).

catalog
A central PDF dictionary – also called the “root” – containing document-wide parameters and pointers to many other information.

contents
“A content stream is a PDF object with an attached stream, whose data consists of a sequence of instructions describing the graphical elements to be painted on a page.” (Adobe PDF References p. 151). For an overview of the mini-language used in these streams see chapter “Operator Summary” on page 985 of the Adobe PDF References. A PDF page can have none to many contents objects. If it has none, the page is empty.
PyMuPDF Documentation, Release 1.18.8

(but still may show annotations). If it has several, they will be interpreted in sequence as if their instructions had been present in one such object (i.e. like in a concatenated string). It should be noted that there are more stream object types which use the same syntax: e.g. appearance dictionaries associated with annotations and Form XObjects.

**resources**

A dictionary containing references to any resources (like images or fonts) required by a PDF page (required, inheritable, Adobe PDF References p. 145) and certain other objects (Form XObjects). This dictionary appears as a sub-dictionary in the object definition under the key /Resources. Being an inheritable object type, there may exist “parent” resources for all pages or certain subsets of pages.

**dictionary**

A PDF object type, which is somewhat comparable to the same-named Python notion: “A dictionary object is an associative table containing pairs of objects, known as the dictionary’s entries. The first element of each entry is the key and the second element is the value. The key must be a name (...). The value can be any kind of object, including another dictionary. A dictionary entry whose value is null (...) is equivalent to an absent entry.” (Adobe PDF References p. 59).

Dictionaries are the most important object type in PDF. Here is an example (describing a page):

```plaintext
<<
/Contents 40 0 R % value: an indirect object
/Type/Page % value: a name object
/MediaBox[0 0 595.32 841.92] % value: an array object
/Rotate 0 % value: a number object
/Parent 12 0 R % value: an indirect object
/Resources<<
  /ExtGState<</R7 26 0 R>>
  /Font<<
    /R8 27 0 R/R10 21 0 R/R12 24 0 R/R14 15 0 R
    /R17 4 0 R/R20 30 0 R/R23 7 0 R /R27 20 0 R
  >>
  /ProcSet[/PDF/Text] % value: array of two name objects
>>
/Annots[55 0 R] % value: array, one entry (indirect object)
>>

Contents, Type, MediaBox, etc. are keys, 40 0 R, Page, [0 0 595.32 841.92], etc. are the respective values. The strings “<<” and “>>” are used to enclose object definitions.

This example also shows the syntax of nested dictionary values: Resources has an object as its value, which in turn is a dictionary with keys like ExtGState (with the value </R7 26 0 R>>, which is another dictionary), etc.

**page**

A PDF page is a dictionary object which defines one page in a PDF, see Adobe PDF References p. 145.

**pagetree**

“The pages of a document are accessed through a structure known as the page tree, which defines the ordering of pages in the document. The tree structure allows PDF consumer applications, using only limited memory, to quickly open a document containing thousands of pages. The tree contains nodes of two types: intermediate nodes, called page tree nodes, and leaf nodes, called page objects.” (Adobe PDF References p. 143).

While it is possible to list all page references in just one array, PDFs with many pages are often created using balanced tree structures (“page trees”) for faster access to any single page. In relation to the total number of pages, this can reduce the average page access time by page number from a linear to some logarithmic order of magnitude.

For fast page access, MuPDF can use its own array in memory – independently from what may or may not be present in the document file. This array is indexed by page number and therefore much faster than even the
access via a perfectly balanced page tree.

**object**

Similar to Python, PDF supports the notion *object*, which can come in eight basic types: boolean values, integer and real numbers, strings, names, arrays, dictionaries, streams, and the null object (Adobe PDF References p. 51). Objects can be made identifiable by assigning a label. This label is then called *indirect* object. PyMuPDF supports retrieving definitions of indirect objects via their cross reference number via `Document.xref_object()`.

**stream**

A PDF *object* type which is followed by a sequence of bytes, similar to a Python *string* or rather *bytes*. “However, a PDF application can read a stream incrementally, while a string must be read in its entirety. Furthermore, a stream can be of unlimited length, whereas a string is subject to an implementation limit. For this reason, objects with potentially large amounts of data, such as images and page descriptions, are represented as streams.”

“*A stream consists of a dictionary followed by zero or more bytes bracketed between the keywords stream and endstream*”:

```
nnn 0 obj
<<
  dictionary definition
>>
stream
(zero or more bytes)
endstream
endobj
```

See Adobe PDF References p. 60. PyMuPDF supports retrieving stream content via `Document.xrefStream()`. Use `Document.is_stream()` to determine whether an object is of stream type.

**unitvector**

A mathematical notion meaning a vector of norm (“length”) 1 – usually the Euclidean norm is implied. In PyMuPDF, this term is restricted to `Point` objects, see `Point.unit`.

**xref**

Abbreviation for cross-reference number: this is an integer unique identification for objects in a PDF. There exists a cross-reference table (which may physically consist of several separate segments) in each PDF, which stores the relative position of each object for quick lookup. The cross-reference table is one entry longer than the number of existing object: item zero is reserved and must not be used in any way. Many PyMuPDF classes have an `xref` attribute (which is zero for non-PDFs), and one can find out the total number of objects in a PDF via `Document.xref_length() - 1`.

**resolution**

Images and `Pixmap` objects may contain resolution information provided as “dots per inch”, dpi, in each direction (horizontal and vertical). When MuPDF reads an image form a file or from a PDF object, it will parse this information and put it in `Pixmap.xres, Pixmap.yres`, respectively. When it finds not meaningful information in the input (like non-positive values or values exceeding 4800), it will use “sane” defaults instead. The usual default value is 96, but it may also be 72 in some cases (e.g. for JPX images).

**OCPD**

Optional content properties dictionary - a sub *dictionary* of the PDF *catalog*. The central place to store optional content information, which is identified by the key `/OCProperties`. This dictionary has two required and one optional entry: (1) `/OCGs`, required, an array listing all optional content groups, (2) `/D`, required, the default optional content configuration dictionary (OCCD), (3) `/Configs`, optional, an array of alternative OCCDs.

**OCCD**

Optional content configuration dictionary - a PDF *dictionary* inside the PDF OCPD. It stores a setting of ON / OFF states of OCGs and how they are presented to a PDF viewer program. Selecting a configuration is quick way to achieve temporary mass visibility state changes. After opening a PDF, the `/D` configuration of the OCPD
is always activated. Viewer should offer a way to switch between the /D, or one of the optional configurations contained in array /Configs.

**OCG**

Optional content group – a dictionary object used to control the visibility of other PDF objects like images or annotations. Independently on which page they are defined, objects with the same OCG can simultaneously be shown or hidden by setting their OCG to ON or OFF. This can be achieved via the user interface provided by many PDF viewers (Adobe Acrobat), or programmatically.

**OCMD**

Optional content membership dictionary – a dictionary object which can be used like an OCG: it has a visibility state. The visibility of an OCMD is computed: it is a logical expression, which uses the state of one or more OCGs to produce a boolean value. The expression’s result is interpreted as ON (true) or OFF (false).
CHAPTER 10

Constants and Enumerations

Constants and enumerations of MuPDF as implemented by PyMuPDF. Each of the following variables is accessible as `fitz.variable`.

10.1 Constants

**Base14_Fonts**
Predefined Python list of valid PDF Base 14 Fonts.

Return type list

**csRGB**
Predefined RGB colorspace `fitz.Colorspace(fitz.CS_RGB)`.

Return type Colorspace

**csGRAY**
Predefined GRAY colorspace `fitz.Colorspace(fitz.CS_GRAY)`.

Return type Colorspace

**csCMYK**
Predefined CMYK colorspace `fitz.Colorspace(fitz.CS_CMYK)`.

Return type Colorspace

**CS_RGB**
1 – Type of Colorspace is RGBA

Return type int

**CS_GRAY**
2 – Type of Colorspace is GRAY

Return type int

**CS_CMYK**
3 – Type of Colorspace is CMYK
Return type int

VersionBind
‘x.xx.x’ – version of PyMuPDF (these bindings)

Return type string

VersionFitz
‘x.xxx’ – version of MuPDF

Return type string

VersionDate
ISO timestamp YYYY-MM-DD HH:MM:SS when these bindings were built.

Return type string

Note: The docstring of fitz contains information of the above which can be retrieved like so: print(fitz.__doc__), and should look like: PyMuPDF 1.10.0: Python bindings for the MuPDF 1.10 library, built on 2016-11-30 13:09:13.

version
(VersionBind, VersionFitz, timestamp) – combined version information where timestamp is the generation point in time formatted as “YYYYMMDDhhmmss”.

Return type tuple

10.2 Document Permissions

<table>
<thead>
<tr>
<th>Code</th>
<th>Permitted Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>PDF_PERM_PRINT</td>
<td>Print the document</td>
</tr>
<tr>
<td>PDF_PERM_MODIFY</td>
<td>Modify the document’s contents</td>
</tr>
<tr>
<td>PDF_PERM_COPY</td>
<td>Copy or otherwise extract text and graphics</td>
</tr>
<tr>
<td>PDF_PERM_ANNOTATE</td>
<td>Add or modify text annotations and interactive form fields</td>
</tr>
<tr>
<td>PDF_PERM_FORM</td>
<td>Fill in forms and sign the document</td>
</tr>
<tr>
<td>PDF_PERM_ACCESSIBILITY</td>
<td>Obsolete, always permitted</td>
</tr>
<tr>
<td>PDF_PERM_ASSEMBLE</td>
<td>Insert, rotate, or delete pages, bookmarks, thumbnail images</td>
</tr>
<tr>
<td>PDF_PERM_PRINT_HQ</td>
<td>High quality printing</td>
</tr>
</tbody>
</table>

10.3 PDF encryption method codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>PDF_ENCRYPT_KEEP</td>
<td>do not change</td>
</tr>
<tr>
<td>PDF_ENCRYPT_NONE</td>
<td>remove any encryption</td>
</tr>
<tr>
<td>PDF_ENCRYPT_RC4_40</td>
<td>RC4 40 bit</td>
</tr>
<tr>
<td>PDF_ENCRYPT_RC4_128</td>
<td>RC4 128 bit</td>
</tr>
<tr>
<td>PDF_ENCRYPT_AES_128</td>
<td>Advanced Encryption Standard 128 bit</td>
</tr>
<tr>
<td>PDF_ENCRYPT_AES_256</td>
<td>Advanced Encryption Standard 256 bit</td>
</tr>
<tr>
<td>PDF_ENCRYPT_UNKNOWN</td>
<td>unknown</td>
</tr>
</tbody>
</table>
10.4 Font File Extensions

The table shows file extensions you should use when extracting fonts from a PDF file.

<table>
<thead>
<tr>
<th>Ext</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ttf</td>
<td>TrueType font</td>
</tr>
<tr>
<td>pfa</td>
<td>Postscript for ASCII font (various subtypes)</td>
</tr>
<tr>
<td>cff</td>
<td>Type1C font (compressed font equivalent to Type1)</td>
</tr>
<tr>
<td>cid</td>
<td>character identifier font (postscript format)</td>
</tr>
<tr>
<td>otf</td>
<td>OpenType font</td>
</tr>
<tr>
<td>n/a</td>
<td>built-in font (PDF Base 14 Fonts or CJK: cannot be extracted)</td>
</tr>
</tbody>
</table>

10.5 Text Alignment

TEXT_ALIGN_LEFT
0 – align left.

TEXT_ALIGN_CENTER
1 – align center.

TEXT_ALIGN_RIGHT
2 – align right.

TEXT_ALIGN_JUSTIFY
3 – align justify.

10.6 Preserve Text Flags

Options controlling the amount of data a text device parses into a TextPage.

TEXT_PRESERVE_LIGATURES
1 – If set, ligatures are passed through to the application in their original form. Otherwise ligatures are expanded into their constituent parts, e.g. the ligature ffi is expanded into three separate characters f, f and i.

TEXT_PRESERVE_WHITESPACE
2 – If set, whitespace is passed through to the application in its original form. Otherwise any type of horizontal whitespace (including horizontal tabs) will be replaced with space characters of variable width.

TEXT_PRESERVE_IMAGES
4 – If set, then images will be stored in the structured text structure.

TEXT_INHIBIT_SPACES
8 – If set, we will not try to add missing space characters where there are large gaps between characters.

TEXT_DEHYPHENATE
16 – Ignore hyphens at line ends and join with next line. Used mainly with search function.

TEXT_PRESERVE_SPANS
32 – Generate a new line for every span. Not used in PyMuPDF.
### 10.7 Link Destination Kinds

Possible values of `linkDest.kind` (link destination kind). For details consult *Adobe PDF References*, chapter 8.2 on pp. 581.

**LINK_NONE**
0 – No destination. Indicates a dummy link.

Return type  int

**LINK_GOTO**
1 – Points to a place in this document.

Return type  int

**LINK_URI**
2 – Points to a URI – typically a resource specified with internet syntax.

Return type  int

**LINK_LAUNCH**
3 – Launch (open) another file (of any “executable” type).

Return type  int

**LINK_NAMED**
4 – points to a named location.

Return type  int

**LINK_GOTOR**
5 – Points to a place in another PDF document.

Return type  int

### 10.8 Link Destination Flags

**Note:** The rightmost byte of this integer is a bit field, so test the truth of these bits with the & operator.

**LINK_FLAG_L_VALID**
1 (bit 0) Top left x value is valid

Return type  bool

**LINK_FLAG_T_VALID**
2 (bit 1) Top left y value is valid

Return type  bool

**LINK_FLAG_R_VALID**
4 (bit 2) Bottom right x value is valid

Return type  bool

**LINK_FLAG_B_VALID**
8 (bit 3) Bottom right y value is valid

Return type  bool
**LINK_FLAG_FIT_H**

16 (bit 4) Horizontal fit

**Return type** bool

**LINK_FLAG_FIT_V**

32 (bit 5) Vertical fit

**Return type** bool

**LINK_FLAG_R_IS_ZOOM**

64 (bit 6) Bottom right x is a zoom figure

**Return type** bool

## 10.9 Annotation Related Constants

See chapter 8.4.5, pp. 615 of the *Adobe PDF References* for details.

### 10.9.1 Annotation Types

These identifiers also cover links and widgets: the PDF specification technically handles them all in the same way, whereas MuPDF (and PyMuPDF) treats them as three basically different types of objects.

<table>
<thead>
<tr>
<th>Constant</th>

<td>2</td>
</tr>
<tr>
<td>STAMP_Departmental</td>
<td>3</td>
</tr>
<tr>
<td>STAMP_Experimental</td>
<td>4</td>
</tr>
<tr>
<td>STAMP_Expired</td>
<td>5</td>
</tr>
<tr>
<td>STAMP_Final</td>
<td>6</td>
</tr>
<tr>
<td>STAMP_ForComment</td>
<td>7</td>
</tr>
<tr>
<td>STAMP_ForPublicRelease</td>
<td>8</td>
</tr>
<tr>
<td>STAMP_NotApproved</td>
<td>9</td>
</tr>
<tr>
<td>STAMP_NotForPublicRelease</td>
<td>10</td>
</tr>
<tr>
<td>STAMP_Sold</td>
<td>11</td>
</tr>
<tr>
<td>STAMP_TopSecret</td>
<td>12</td>
</tr>
<tr>
<td>STAMP_Draft</td>
<td>13</td>
</tr>
</tbody>
</table>
Since the introduction of methods involving colors (like `Page.draw_circle()`), a requirement may be to have access to predefined colors.

The fabulous GUI package `wxPython` has a database of over 540 predefined RGB colors, which are given more or less memorizable names. Among them are not only standard names like “green” or “blue”, but also “turquoise”, “skyblue”, and 100 (not only 50 …) shades of “gray”, etc.

We have taken the liberty to copy this database (a list of tuples) modified into PyMuPDF and make its colors available as PDF compatible float triples: for `wxPython`’s (“WHITE”, 255, 255, 255) we return (1.0, 1.0, 1.0), which can be directly used in color and fill parameters. We also accept any mixed case of “wHiTe” to find a color.

### 11.1 Function `getColor()`

As the color database may not be needed very often, one additional import statement seems acceptable to get access to it:

```python
>>> # "getColor" is the only method you really need
>>> from fitz.utils import getColor
>>> getColor("aliceblue")
(0.9411764705882353, 0.9725490196078431, 1.0)
>>> #
>>> # to get a list of all existing names
>>> from fitz.utils import getColorList
>>> cl = getColorList()
>>> cl
['ALICEBLUE', 'ANTIQUEWHITE', 'ANTIQUEWHITE1', 'ANTIQUEWHITE2', 'ANTIQUEWHITE3', 'ANTIQUEWHITE4', 'AQUAMARINE', 'AQUAMARINE1'] ...
>>> #
>>> # to see the full integer color coding
>>> from fitz.utils import getColorInfoList
>>> il = getColorInfoList()
>>> il
```

(continues on next page)
11.2 Printing the Color Database

If you want to actually see how the many available colors look like, use scripts colordbRGB.py or colordbHSV.py in the examples directory. They create PDFs (already existing in the same directory) with all these colors. Their only difference is sorting order: one takes the RGB values, the other one the Hue-Saturation-Values as sort criteria. This is a screen print of what these files look like.
CHAPTER 12

Appendix 1: Performance

We have tried to get an impression on PyMuPDF’s performance. While we know this is very hard and a fair comparison is almost impossible, we feel that we at least should provide some quantitative information to justify our bold comments on MuPDF’s top performance.

Following are three sections that deal with different aspects of performance:

- document parsing
- text extraction
- image rendering

In each section, the same fixed set of PDF files is being processed by a set of tools. The set of tools varies – for reasons we will explain in the section.

Here is the list of files we are using. Each file name is accompanied by further information: size in bytes, number of pages, number of bookmarks (toc entries), number of links, text size as a percentage of file size, KB per page, PDF version and remarks. text % and KB index are indicators for whether a file is text or graphics oriented.

<table>

</tbody>
</table>

Decimal point and comma follow European convention

E.g. Adobe.pdf and PyMuPDF.pdf are clearly text oriented, all other files contain many more images.
12.1 Part 1: Parsing

How fast is a PDF file read and its content parsed for further processing? The sheer parsing performance cannot directly be compared, because batch utilities always execute a requested task completely, in one go, front to end. *pdfrw* too, has a lazy strategy for parsing, meaning it only parses those parts of a document that are required in any moment.

To yet find an answer to the question, we therefore measure the time to copy a PDF file to an output file with each tool, and doing nothing else.

These were the tools

All tools are either platform independent, or at least can run both, on Windows and Unix / Linux (pdftk).

*Poppler* is missing here, because it specifically is a Linux tool set, although we know there exist Windows ports (created with considerable effort apparently). Technically, it is a C/C++ library, for which a Python binding exists – in so far somewhat comparable to PyMuPDF. But Poppler in contrast is tightly coupled to *Qt* and *Cairo*. We may still include it in future, when a more handy Windows installation is available. We have seen however some analysis, that hints at a much lower performance than MuPDF. Our comparison of text extraction speeds also show a much lower performance of Poppler’s PDF code base *Xpdf*.

Image rendering of MuPDF also is about three times faster than the one of Xpdf when comparing the command line tools *mudraw* of MuPDF and *pdftopng* of Xpdf – see part 3 of this chapter.

<table>
<thead>
<tr>
<th>Tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PyMuPDF</td>
<td>tool of this manual, appearing as “fitz” in reports</td>
</tr>
<tr>
<td>pdfrw</td>
<td>a pure Python tool, is being used by rst2pdf, has interface to ReportLab</td>
</tr>
<tr>
<td>PyPDF2</td>
<td>a pure Python tool with a very complete function set</td>
</tr>
<tr>
<td>pdftk</td>
<td>a command line utility with numerous functions</td>
</tr>
</tbody>
</table>

This is how each of the tools was used:

**PyMuPDF**:

```python
doc = fitz.open("input.pdf")
doc.save("output.pdf")
```

**pdfrw**:

```python
doc = PdfReader("input.pdf")
writer = PdfWriter()
writer.trailer = doc
writer.write("output.pdf")
```

**PyPDF2**:

```python
pdfmerge = PyPDF2.PdfFileMerger()
pdfmerge.append("input.pdf")
pdfmerge.write("output.pdf")
pdfmerge.close()
```

**pdftk**:

```bash
pdftk input.pdf output output.pdf
```

Observations
These are our run time findings (in **seconds**, please note the European number convention: meaning of decimal point and comma is reversed):

</tr>
</tbody>
</table>

If we leave out the Adobe manual, this table looks like
PyMuPDF is by far the fastest: on average 4.5 times faster than the second best (the pure Python tool pdfrw, chapeau pdfrw!), and almost 20 times faster than the command line tool pdftk.

Where PyMuPDF only requires less than 13 seconds to process all files, pdftk affords itself almost 4 minutes.

By far the slowest tool is PyPDF2 – it is more than 66 times slower than PyMuPDF and 15 times slower than pdfrw! The main reason for PyPDF2’s bad look comes from the Adobe manual. It obviously is slowed down by the linear file structure and the immense amount of bookmarks of this file. If we take out this special case, then PyPDF2 is only 21.5 times slower than PyMuPDF, 4.5 times slower than pdfrw and 1.2 times slower than pdftk.

If we look at the output PDFs, there is one surprise:

Each tool created a PDF of similar size as the original. Apart from the Adobe case, PyMuPDF always created the smallest output.

Adobe’s manual is an exception: The pure Python tools pdfrw and PyPDF2 reduced its size by more than 20% (and yielded a document which is no longer linearized)!

PyMuPDF and pdftk in contrast drastically increased the size by 40% to about 50 MB (also no longer linearized).

So far, we have no explanation of what is happening here.

### 12.2 Part 2: Text Extraction

We also have compared text extraction speed with other tools.

The following table shows a run time comparison. PyMuPDF’s methods appear as “fitz (TEXT)” and “fitz (JSON)” respectively. The tool pdfiotext.exe of the Xpdf toolset appears as “xpdf”.

<table>
<thead>
<tr>
<th>File</th>
<th>fitz</th>
<th>pdfrw</th>
<th>pdftk</th>
<th>PyPDF2</th>
</tr>
</thead>
<tbody>
<tr>

</table>
• **extractText()**: basic text extraction without layout re-arrangement (using `GetText(., output = "text")`)
• **pdftotext**: a command line tool of the *Xpdf* toolset (which also is the basis of *Poppler*’s library)
• **extractJSON()**: text extraction with layout information (using `GetText(., output = "json")`)
• **pdfminer**: a pure Python PDF tool specialized on text extraction tasks

All tools have been used with their most basic, fanciless functionality – no layout re-arrangements, etc.

For demonstration purposes, we have included a version of `GetText(doc, output = "json")`, that also re-arranges the output according to occurrence on the page.

Here are the results using the same test files as above (again: decimal point and comma reversed):

<table>

</tbody>
</table>

Again, (Py-) MuPDF is the fastest around. It is 2.3 to 2.6 times faster than xpdf.

*pdfminer*, as a pure Python solution, of course is comparatively slow: MuPDF is 50 to 60 times faster and xpdf is 23 times faster. These observations in order of magnitude coincide with the statements on this web site.

### 12.3 Part 3: Image Rendering

We have tested rendering speed of MuPDF against the *pdftopng.exe*, a command line tool of the *Xpdf* toolset (the PDF code basis of *Poppler*).

MuPDF invocation using a resolution of 150 pixels (Xpdf default):
mutool draw -o t%d.png -r 150 file.pdf

PyMuPDF invocation:

```python
zoom = 150.0 / 72.0
mat = fitz.Matrix(zoom, zoom)
def ProcessFile(datei):
    print "processing":, datei
doc=fitz.open(datei)
    for p in fitz.Pages(doc):
        pix = p.get_pixmap(matrix=mat, alpha = False)
        pix.writePNG("t-%s.png" % p.number)
    pix = None
doc.close()
    return
```

Xpdf invocation:

```
pdftopng.exe file.pdf ./
```

The resulting runtimes can be found here (again: meaning of decimal point and comma reversed):
- MuPDF and PyMuPDF are both about 3 times faster than Xpdf.
- The 2% speed difference between MuPDF (a utility written in C) and PyMuPDF is the Python overhead.

Appendix 2: Details on Text Extraction

This chapter provides background on the text extraction methods of PyMuPDF.

Information of interest are

- what do they provide?
- what do they imply (processing time / data sizes)?

13.1 General structure of a TextPage

`TextPage` is one of PyMuPDF’s classes. It is normally created behind the curtain, when `Page` text extraction methods are used, but it is also available directly. In any case, an intermediate class, `DisplayList` must be created first (display lists contain interpreted pages, they also provide the input for `Pixmap` creation). Information contained in a `TextPage` has the following hierarchy. Other than its name suggests, images may optionally also be part of a text page:

```
<page>
  <text block>
    <line>
      <span>
        <char>
      </span>
    </line>
  </text block>
  <image block>
    <img>
  </image block>
</page>
```

A **text page** consists of blocks (= roughly paragraphs).

A **block** consists of either lines and their characters, or an image.

A **line** consists of spans.

A **span** consists of adjacent characters with identical font properties: name, size, flags and color.
13.2 Plain Text

Function `TextPage.extractText()` (or `Page.get_text("text")`) extracts a page’s plain text in original order as specified by the creator of the document (which may not equal a natural reading order).

An example output:

```python
>>> print(page.get_text("text"))
Some text on first page.
```

13.3 BLOCKS

Function `TextPage.extractBLOCKS()` (or `Page.get_text("blocks")`) extracts a page’s text blocks as a list of items like:

```
(x0, y0, x1, y1, "lines in block", block_type, block_no)
```

Where the first 4 items are the float coordinates of the block’s bbox. The lines within each block are concatenated by a new-line character.

This is a high-speed method with enough information to re-arrange the page’s text in natural reading order where required.

Example output:

```python
>>> print(page.get_text("blocks"))
[(50.0, 88.17500305175781, 166.1709747314453, 103.28900146484375, 'Some text on first page.', 0, 0)]
```

13.4 WORDS

Function `TextPage.extractWORDS()` (or `Page.get_text("words")`) extracts a page’s text words as a list of items like:

```
(x0, y0, x1, y1, "word", block_no, line_no, word_no)
```

Where the first 4 items are the float coordinates of the words’s bbox. The last three integers provide some more information on the word’s whereabouts.

This is a high-speed method with enough information to extract text contained in a given rectangle.

Example output:

```python
>>> for word in page.get_text("words"):
    print(word)
(50.0, 88.17500305175781, 78.73200225830078, 103.28900146484375, 'Some', 0, 0, 0)
(81.79000091552734, 88.17500305175781, 99.5219955444336, 103.28900146484375, 'text', 0, 0, 1)
(102.57998748779297, 88.17500305175781, 114.8119881591797, 103.28900146484375, 'on', 0, 0, 2)
(117.86998748779297, 88.17500305175781, 135.5909881591797, 103.28900146484375, 'first', 0, 0, 3)
```

(continues on next page)
13.5 HTML

`TextPage.extractHTML()` (or `Page.get_text("html")`) output fully reflects the structure of the page’s `TextPage` – much like DICT / JSON below. This includes images, font information and text positions. If wrapped in HTML header and trailer code, it can readily be displayed by an internet browser. Our above example:

```python
>>> for line in page.get_text("html").splitlines():
    print(line)

<div id="page0" style="position:relative;width:300pt;height:350pt;background-color:white">
<p style="position:absolute;white-space:pre;margin:0;padding:0;top:88pt;left:50pt">Some text on first page.</p>
</div>
```

13.6 Controlling Quality of HTML Output

While HTML output has improved a lot in MuPDF v1.12.0, it is not yet bug-free: we have found problems in the areas font support and image positioning.

- HTML text contains references to the fonts used of the original document. If these are not known to the browser (a fat chance!), it will replace them with others; the results will probably look awkward. This issue varies greatly by browser – on my Windows machine, MS Edge worked just fine, whereas Firefox looked horrible.

- For PDFs with a complex structure, images may not be positioned and / or sized correctly. This seems to be the case for rotated pages and pages, where the various possible page bbox variants do not coincide (e.g. `MediaBox != CropBox`). We do not know yet, how to address this – we filed a bug at MuPDF’s site.

To address the font issue, you can use a simple utility script to scan through the HTML file and replace font references. Here is a little example that replaces all fonts with one of the PDF Base 14 Fonts: serifed fonts will become “Times”, non-serifed “Helvetica” and monospaced will become “Courier”. Their respective variations for “bold”, “italic”, etc. are hopefully done correctly by your browser:

```python
import sys
filename = sys.argv[1]
# original html text string
otext = open(filename).read()
posl = 0 # search start position
font_serif = "font-family:Times" # enter ...
font_sans = "font-family:Helvetica" # ... your choices ...
font_mono = "font-family:Courier" # ... here
found_one = False # true if search successfull

while True:
    pos0 = otext.find("font-family:", pos1) # start of a font spec
    if pos0 < 0:
        # none found - we are done
        break
    pos1 = otext.find(";", pos0) # end of font spec
    test = otext[pos0 : pos1] # complete font spec string
```
testn = ""  # the new font spec string
if test.endswith(",serif"):
    testn = font_serif  # font with serifs?
elif test.endswith(",sans-serif"):
    testn = font_sans  # use Times instead
elif test.endswith(",monospace"):
    testn = font_mono  # use Helvetica
    testn = font_sans  # monospaced font?
else:
    if testn != "":  # any of the above found?
        otext = otext.replace(test, testn)  # change the source
        found_one = True  # start over
        pos1 = 0
if found_one:
    ofile = open(filename + ".html", "w")
    ofile.write(otext)
    ofile.close()
else:
    print(Warning: could not find any font specs!"

13.7 DICT (or JSON)

TextPage.extractDICT() (or Page.get_text("dict")) output fully reflects the structure of a TextPage and provides image content and position details (bbox – boundary boxes in pixel units) for every block and line. This information can be used to present text in another reading order if required (e.g. from top-left to bottom-right). Images are stored as bytes (bytearray in Python 2) for DICT output and base64 encoded strings for JSON output.

For a visualisation of the dictionary structure have a look at Dictionary Structure of extractDICT() and extractRAW- DICT().

Here is how this looks like:

```json
{
    "width": 300.0,
    "height": 350.0,
    "blocks": [{
        "type": 0,
        "bbox": [50.0, 88.17500305175781, 166.1709747314453, 103.28900146484375],
        "lines": [{
            "wmode": 0,
            "dir": [1.0, 0.0],
            "bbox": [50.0, 88.17500305175781, 166.1709747314453, 103.28900146484375],
            "spans": [{
                "size": 11.0,
                "flags": 0,
                "font": "Helvetica",
                "color": 0,
                "text": "Some text on first page."
            },
            [50.0, 88.17500305175781, 166.1709747314453, 103.28900146484375]
        }]
    }]
}
13.8 RAWDICT

TextPage.extractRAWDICT() (or Page.get_text("rawdict")) is an information superset of DICT and takes the detail level one step deeper. It looks exactly like the above, except that the “text” items (string) are replaced by “chars” items (list). Each “chars” entry is a character dict. For example, here is what you would see in place of item “text”: “Text in black color.” above:

```
"chars": [{
  "origin": [50.0, 100.0],
  "bbox": [50.0, 88.17500305175781, 57.336997985839844, 103.28900146484375],
  "c": "S"
}, {
  "origin": [57.33700180053711, 100.0],
  "bbox": [57.33700180053711, 88.17500305175781, 63.4530029296875, 103.28900146484375],
  "c": "o"
}, {
  "origin": [63.4530029296875, 100.0],
  "bbox": [63.4530029296875, 88.17500305175781, 72.61600494384766, 103.28900146484375],
  "c": "m"
}, {
  "origin": [72.61600494384766, 100.0],
  "bbox": [72.61600494384766, 88.17500305175781, 78.73200225830078, 103.28900146484375],
  "c": "e"
}, {
  "origin": [78.73200225830078, 100.0],
  "bbox": [78.73200225830078, 88.17500305175781, 81.79000091552734, 103.28900146484375],
  "c": "="
}< ... deleted ... >
}, {
  "origin": [163.11297607421875, 100.0],
  "bbox": [163.11297607421875, 88.17500305175781, 166.1709747314453, 103.28900146484375],
  "c": "."
}],
```

13.9 XML

The TextPage.extractXML() (or Page.get_text("xml")) version extracts text (no images) with the detail level of RAWDICT:

```python
>>> for line in page.get_text("xml").splitlines():
    print(line)
<page id="page0" width="300" height="350">
<block bbox="50 88.175 166.17098 103.289">
<line bbox="50 88.175 166.17098 103.289" wmode="0" dir="1 0">
<font name="Helvetica" size="11">
<char quad="50 88.175 57.3369999 88.175 50 103.289 57.3369999 103.289" x="50" y="100" color="#000000" c="S"/>
<char quad="57.337 88.175 63.453004 88.175 57.337 103.289 63.453004 103.289" x="57.337" "
```

(continues on next page)
Note: We have successfully tested lxml to interpret this output.

13.10 XHTML

`TextPage.extractXHTML()` (or `Page.get_text("xhtml")`) is a variation of TEXT but in HTML format, containing the bare text and images ("semantic" output):

```html
<div id="page0">
<p>Some text on first page.</p>
</div>
```

13.11 Text Extraction Flags Defaults

(New in version 1.16.2) Method `Page.get_text()` supports a keyword parameter `flags (int)` to control the amount and the quality of extracted data. The following table shows the defaults settings (flags parameter omitted or None) for each extraction variant. If you specify flags with a value other than `None`, be aware that you must set all desired options. A description of the respective bit settings can be found in Preserve Text Flags.

<table>
<thead>
<tr>
<th>Indicator</th>
<th>text</th>
<th>html</th>
<th>xhtml</th>
<th>xml</th>
<th>dict</th>
<th>rawdict</th>
<th>words</th>
<th>blocks</th>
</tr>
</thead>
<tbody>
<tr>
<td>preserve ligatures</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>preserve whitespace</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>preserve images</td>
<td>n/a</td>
<td>1</td>
<td>n/a</td>
<td>1</td>
<td>1</td>
<td>n/a</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>inhibit spaces</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>dehyphenate</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

- “json” is handled exactly like “dict” and is hence left out.
- An “n/a” specification means a value of 0 and setting this bit never has any effect on the output (but an adverse effect on performance).
• If you are not interested in images when using an output variant which includes them by default, then by all means set the respective bit off: You will experience a better performance and much lower space requirements.

To show the effect of `TEXT_INHIBIT_SPACES` have a look at this example:

```python
>>> print(page.get_text("text"))
Hallo!
More text
is following
in English
... let's see
what happens.
>>> print(page.get_text("text", flags=fitz.TEXT_INHIBIT_SPACES))
Hallo!
More text
is following
in English
... let's see
what happens.
```

## 13.12 Performance

The text extraction methods differ significantly: in terms of information they supply, and in terms of resource requirements and runtimes. Generally, more information of course means that more processing is required and a higher data volume is generated.

**Note:** Especially images have a very significant impact. Make sure to exclude them (via the `flags` parameter) whenever you do not need them. To process the below mentioned 2'700 total pages with default flags settings required 160 seconds across all extraction methods. When all images where excluded, less than 50% of that time (77 seconds) were needed.

To begin with, all methods are very fast in relation to other products out there in the market. In terms of processing speed, we are not aware of a faster (free) tool. Even the most detailed method, RAWDICT, processes all 1'310 pages of the *Adobe PDF References* in less than 5 seconds (simple text needs less than 2 seconds here).

The following table shows average relative speeds (“RSpeed”, baseline 1.00 is TEXT), taken across ca. 1400 text-heavy and 1300 image-heavy pages.

<table>
<thead>
<tr>
<th>Method</th>
<th>RSpeed</th>
<th>Comments</th>
<th>no images</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXT</td>
<td>1.00</td>
<td>no images, plain text, line breaks</td>
<td>1.00</td>
</tr>
<tr>
<td>BLOCKS</td>
<td>1.00</td>
<td>image bboxes (only), block level text with bboxes, line breaks</td>
<td>1.00</td>
</tr>
<tr>
<td>WORDS</td>
<td>1.02</td>
<td>no images, word level text with bboxes</td>
<td>1.02</td>
</tr>
<tr>
<td>XML</td>
<td>2.72</td>
<td>no images, char level text, layout and font details</td>
<td>2.72</td>
</tr>
<tr>
<td>XHTML</td>
<td>3.32</td>
<td>base64 images, span level text, no layout info</td>
<td>1.00</td>
</tr>
<tr>
<td>HTML</td>
<td>3.54</td>
<td>base64 images, span level text, layout and font details</td>
<td>1.01</td>
</tr>
<tr>
<td>DICT</td>
<td>3.93</td>
<td>binary images, span level text, layout and font details</td>
<td>1.04</td>
</tr>
<tr>
<td>RAWDICT</td>
<td>4.50</td>
<td>binary images, char level text, layout and font details</td>
<td>1.68</td>
</tr>
</tbody>
</table>

As mentioned: when excluding all images (last column), the relative speeds are changing drastically: except RAWDICT and XML, the other methods are almost equally fast, and RAWDICT requires 40% less execution time than the now slowest XML.
Look at chapter Appendix 1 for more performance information.
Appendix 3: Considerations on Embedded Files

This chapter provides some background on embedded files support in PyMuPDF.

14.1 General

Starting with version 1.4, PDF supports embedding arbitrary files as part (“Embedded File Streams”) of a PDF document file (see chapter 3.10.3, pp. 184 of the Adobe PDF References).

In many aspects, this is comparable to concepts also found in ZIP files or the OLE technique in MS Windows. PDF embedded files do, however, not support directory structures as does the ZIP format. An embedded file can in turn contain embedded files itself.

Advantages of this concept are that embedded files are under the PDF umbrella, benefitting from its permissions / password protection and integrity aspects: all data, which a PDF may reference or even may be dependent on, can be bundled into it and so form a single, consistent unit of information.

In addition to embedded files, PDF 1.7 adds collections to its support range. This is an advanced way of storing and presenting meta information (i.e. arbitrary and extensible properties) of embedded files.

14.2 MuPDF Support

After adding initial support for collections (portfolios) and /EmbeddedFiles in MuPDF version 1.11, this support was dropped again in version 1.15.

As a consequence, the cli utility mutool no longer offers access to embedded files.

PyMuPDF – having implemented an /EmbeddedFiles API in response in its version 1.11.0 – was therefore forced to change gears starting with its version 1.16.0 (we never published a MuPDF v1.15.x compatible PyMuPDF).

We are now maintaining our own code basis supporting embedded files. This code makes use of basic MuPDF dictionary and array functions only.
14.3 PyMuPDF Support

We continue to support the full old API with respect to embedded files – with only minor, cosmetic changes.

There even also is a new function, which delivers a list of all names under which embedded data are registered in a PDF, `Document.embfile_names()`.
15.1 PDF Base 14 Fonts

The following 14 built-in font names **must be supported by every PDF viewer** application. They are available as a dictionary, which maps their full names and their abbreviations in lower case to the full font basename. Wherever a **fontname** must be provided in PyMuPDF, any **key or value** from the dictionary may be used:

```
In [2]: fitz.Base14_fontdict
Out[2]:
{'courier': 'Courier',
 'courier-oblique': 'Courier-Oblique',
 'courier-bold': 'Courier-Bold',
 'courier-boldoblique': 'Courier-BoldOblique',
 'helvetica': 'Helvetica',
 'helvetica-oblique': 'Helvetica-Oblique',
 'helvetica-bold': 'Helvetica-Bold',
 'helvetica-boldoblique': 'Helvetica-BoldOblique',
 'times-roman': 'Times-Roman',
 'times-italic': 'Times-Italic',
 'times-bold': 'Times-Bold',
 'times-bolditalic': 'Times-BoldItalic',
 'symbol': 'Symbol',
 'zapfdingbats': 'ZapfDingbats',
 'helv': 'Helvetica',
 'heit': 'Helvetica-Oblique',
 'hebo': 'Helvetica-Bold',
 'hebi': 'Helvetica-BoldOblique',
 'cour': 'Courier',
 'coit': 'Courier-Oblique',
 'cobo': 'Courier-Bold',
 'cobi': 'Courier-BoldOblique',
 'tiro': 'Times-Roman',
 'tibo': 'Times-Bold',
 'tiit': 'Times-Italic',
```

(continues on next page)
In contrast to their obligation, not all PDF viewers support these fonts correctly and completely – this is especially true for Symbol and ZapfDingbats. Also, the glyph (visual) images will be specific to every reader.

To see how these fonts can be used – including the CJK built-in fonts – look at the table in `Page.insertFont()`.

### 15.2 Adobe PDF References

This PDF Reference manual published by Adobe is frequently quoted throughout this documentation. It can be viewed and downloaded from [here](#). There is a newer version of this, which can be found [here](#). Redaction annotations are an example contained in this one, but not in the earlier version.

### 15.3 Using Python Sequences as Arguments in PyMuPDF

When PyMuPDF objects and methods require a Python list of numerical values, other Python sequence types are also allowed. Python classes are said to implement the sequence protocol, if they have a `_getitem_()` method.

This basically means, you can interchangeably use Python list or tuple or even `array.array`, `numpy.array` and `bytearray` types in these cases.

For example, specifying a sequence “s” in any of the following ways

- \( s = [1, 2] \)
- \( s = (1, 2) \)
- \( s = array.array(\text{“i”}, (1, 2)) \)
- \( s = numpy.array((1, 2)) \)
- \( s = bytearray((1, 2)) \)

will make it usable in the following example expressions:

- \( fitz.Point(s) \)
- \( fitz.Point(x, y) + s \)
- \( doc.select(s) \)

Similarly with all geometry objects `Rect`, `IRect`, `Matrix` and `Point`.

Because all PyMuPDF geometry classes themselves are special cases of sequences, they (with the exception of `Quad` – see below) can be freely used where numerical sequences can be used, e.g. as arguments for functions like `list()`, `tuple()`, `array.array()` or `numpy.array()`. Look at the following snippet to see this work.
>>> import fitz, array, numpy as np
>>> m = fitz.Matrix(1, 2, 3, 4, 5, 6)
>>> list(m)
[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]
>>> tuple(m)
(1.0, 2.0, 3.0, 4.0, 5.0, 6.0)
>>> array.array("f", m)
array([1., 2., 3., 4., 5., 6.])

Note: Quadr is a Python sequence object as well and has a length of 4. Its items however are point_like – not numbers. Therefore, the above remarks do not apply.

15.4 Ensuring Consistency of Important Objects in PyMuPDF

PyMuPDF is a Python binding for the C library MuPDF. While a lot of effort has been invested by MuPDF’s creators to approximate some sort of an object-oriented behavior, they certainly could not overcome basic shortcomings of the C language in that respect.

Python on the other hand implements the OO-model in a very clean way. The interface code between PyMuPDF and MuPDF consists of two basic files: fitz.py and fitz_wrap.c. They are created by the excellent SWIG tool for each new version.

When you use one of PyMuPDF’s objects or methods, this will result in excution of some code in fitz.py, which in turn will call some C code compiled with fitz_wrap.c.

Because SWIG goes a long way to keep the Python and the C level in sync, everything works fine, if a certain set of rules is being strictly followed. For example: never access a Page object, after you have closed (or deleted or set to None) the owning Document. Or, less obvious: never access a page or any of its children (links or annotations) after you have executed one of the document methods select(), delete_page(), insert_page() . . . and more.

But just no longer accessing invalidated objects is actually not enough: They should rather be actively deleted entirely, to also free C-level resources (meaning allocated memory).

The reason for these rules lies in the fact that there is a hierachical 2-level one-to-many relationship between a document and its pages and also between a page and its links / annotations. To maintain a consistent situation, any of the above actions must lead to a complete reset – in Python and, synchronously, in C.

SWIG cannot know about this and consequently does not do it.

The required logic has therefore been built into PyMuPDF itself in the following way.

1. If a page “loses” its owning document or is being deleted itself, all of its currently existing annotations and links will be made unusable in Python, and their C-level counterparts will be deleted and deallocated.

2. If a document is closed (or deleted or set to None) or if its structure has changed, then similarly all currently existing pages and their children will be made unusable, and corresponding C-level deletions will take place.

“Structure changes” include methods like select(), delete_page(), insert_page(), insert_pdf() and so on: all of these will result in a cascade of object deletions.
The programmer will normally not realize any of this. If he, however, tries to access invalidated objects, exceptions will be raised.

Invalidated objects cannot be directly deleted as with Python statements like `del page` or `page = None`, etc. Instead, their `__del__` method must be invoked.

All pages, links and annotations have the property `parent`, which points to the owning object. This is the property that can be checked on the application level: if `obj.parent == None` then the object’s parent is gone, and any reference to its properties or methods will raise an exception informing about this “orphaned” state.

A sample session:

```python
>>> page = doc[n]
>>> annot = page.firstAnnot  # everything works fine
>>> annot.type
[5, 'Circle']
>>> page = None  # this turns 'annot' into an orphan
>>> annot.type
RuntimeError: orphaned object: parent is None

>>> # same happens, if you do this:
>>> annot = doc[n].firstAnnot  # deletes the page again immediately!
>>> annot.type
RuntimeError: orphaned object: parent is None

This shows the cascading effect:

```python
>>> doc = fitz.open("some.pdf")
>>> page = doc[n]
>>> annot = page.firstAnnot
>>> page.rect
fitz.Rect(0.0, 0.0, 595.0, 842.0)
>>> annot.type
[5, 'Circle']
>>> del doc  # or doc = None or doc.close()
>>> page.rect
RuntimeError: orphaned object: parent is None
>>> annot.type
RuntimeError: orphaned object: parent is None
```

Note: Objects outside the above relationship are not included in this mechanism. If you e.g. created a table of contents by `toc = doc.get_toc()`, and later close or change the document, then this cannot and does not change variable `toc` in any way. It is your responsibility to refresh such variables as required.
15.5 Design of Method `Page.show_pdf_page()`

15.5.1 Purpose and Capabilities

The method displays an image of a ("source") page of another PDF document within a specified rectangle of the current ("containing", "target") page.

- **In contrast** to `Page.insertImage()`, this display is vector-based and hence remains accurate across zooming levels.
- **Just like** `Page.insertImage()`, the size of the display is adjusted to the given rectangle.

The following variations of the display are currently supported:

- Bool parameter `keep_proportion` controls whether to maintain the aspect ratio (default) or not.
- Rectangle parameter `clip` restricts the visible part of the source page rectangle. Default is the full page.
- Float `rotation` rotates the display by an arbitrary angle (degrees). If the angle is not an integer multiple of 90, only 2 of the 4 corners may be positioned on the target border if also `keep_proportion` is true.
- Bool parameter `overlay` controls whether to put the image on top (foreground, default) of current page content or not (background).

Use cases include (but are not limited to) the following:

1. “Stamp” a series of pages of the current document with the same image, like a company logo or a watermark.
2. Combine arbitrary input pages into one output page to support “booklet” or double-sided printing (known as “4-up”, “n-up”).
3. Split up (large) input pages into several arbitrary pieces. This is also called “posterization”, because you e.g. can split an A4 page horizontally and vertically, print the 4 pieces enlarged to separate A4 pages, and end up with an A2 version of your original page.

15.5.2 Technical Implementation

This is done using PDF “Form XObjects”, see section 4.9 on page 355 of *Adobe PDF References*. On execution of a `Page.show_pdf_page(rect, src, pno, ... )`, the following things happen:

1. The `resources` and `contents` objects of page `pno` in document `src` are copied over to the current document, jointly creating a new Form XObject with the following properties. The PDF `xref` number of this object is returned by the method.
   a. `/BBox` equals `/Mediabox` of the source page
   b. `/Matrix` equals the identity matrix \([1 \ 0 \ 0 \ 1 \ 0 \ 0]\)
   c. `/Resources` equals that of the source page. This involves a “deep-copy” of hierarchically nested other objects (including fonts, images, etc.). The complexity involved here is covered by MuPDF’s grafting\(^1\) technique functions.

---

\(^1\) MuPDF supports “deep-copying” objects between PDF documents. To avoid duplicate data in the target, it uses so-called “graftmaps”, like a form of scratchpad: for each object to be copied, its `xref` number is looked up in the graftmap. If found, copying is skipped. Otherwise, the new `xref` is recorded and the copy takes place. PyMuPDF makes use of this technique in two places so far: `Document.insert_pdf()` and `Page.show_pdf_page()`. This process is fast and very efficient, because it prevents multiple copies of typically large and frequently referenced data, like images and fonts. However, you may still want to consider using garbage collection (option 4) in any of the following cases:

1. The target PDF is not new / empty: grafting does not check for resource types that already existed (e.g. images, fonts) in the target document
2. Using `Page.show_pdf_page()` for more than one source document: each grafting occurs within one source PDF only, not across multiple.
d. This is a stream object type, and its stream is an exact copy of the combined data of the source page’s /Contents objects.

This step is only executed once per shown source page. Subsequent displays of the same page only create pointers (done in next step) to this object.

2. A second **Form XObject** is then created which the target page uses to invoke the display. This object has the following properties:
   a. /BBox equals the /CropBox of the source page (or clip).
   b. /Matrix represents the mapping of /BBox to the target rectangle.
   c. /XObject references the previous XObject via the fixed name fullpage.
   d. The stream of this object contains exactly one fixed statement: /fullpage Do.

3. The **resources** and **contents** objects of the target page are now modified as follows.
   a. Add an entry to the /XObject dictionary of /Resources with the name fzFrm<n> (with n chosen such that this entry is unique on the page).
   b. Depending on overlay, prepend or append a new object to the page’s /Contents array, containing the statement q fzFrm<n> Do Q.

### 15.6 Redirecting Error and Warning Messages

Since MuPDF version 1.16 error and warning messages can be redirected via an official plugin.

PyMuPDF will put error messages to `sys.stderr` prefixed with the string “mupdf:”. Warnings are internally stored and can be accessed via `fitz.TOOLS.mupdf_warnings()`. There also is a function to empty this store.
16.1 Changes in Version 1.18.8

This is a bug fix version only. We are publishing early because of the potentially widely used functions.

- **Fixed** issue #881. Fixed a memory leak in `Page.insert_image()` when inserting images from files or memory.
- **Fixed** issue #878. `pathlib.Path` objects should now correctly handle file path hierarchies.

16.2 Changes in Version 1.18.7

- **Added** an experimental `Document.subset_fonts()` which reduces the size of eligible fonts based on their use by text in the PDF. Implements #855.
- **Implemented** request #870: `Document.convert_to_pdf()` now also supports PDF documents.
- **Renamed** `Document.write` to `Document.tobytes()` for greater clarity. But the deprecated name remains available for some time.
- **Implemented** request #843: `Document.tobytes()` now supports linearized PDF output. `Document.save()` now also supports writing to Python file objects. In addition, the open function now also supports Python file objects.
- **Fixed** issue #844.
- **Fixed** issue #838.
- **Fixed** issue #823. More logic for better support of OCR-ed text output (Tesseract, ABBYY).
- **Fixed** issue #818.
- **Fixed** issue #814.
- **Added** `Document.get_page_labels()` which returns a list of page label definitions of a PDF.
• **Added** `Document.has_annots()` and `Document.has_links()` to check whether these object types are present anywhere in a PDF.

• **Added** expert low-level functions to simplify inquiry and modification of PDF object sources: `Document.xref_get_keys()` lists the keys of object `xref`, `Document.xref_get_key()` returns type and content of a key, and `Document.xref_set_key()` modifies the key’s value.

• **Added** parameter `thumbnails` to `Document.scrub()` to also allow removing page thumbnail images.

• **Improved** documentation for how to add valid text marker annotations for non-horizontal text.

We continued the process of renaming methods and properties from “mixedCase” to “snake_case”. Documentation usually mentions the new names only, but old, deprecated names remain available for some time.

### 16.3 Changes in Version 1.18.6

- **Fixed** issue #812.

- **Fixed** issue #793. Invalid document metadata previously prevented opening some documents at all. This error has been removed.

- **Fixed** issue #792. Text search and text extraction will make no rectangle containment checks at all if the default `clip=None` is used.

- **Fixed** issue #785.

- **Fixed** issue #780. Corrected a parameter check error.

- **Fixed** issue #779. Fixed typo

- **Added** an option to set the desired line height for text boxes. Implements #804.

- **Changed** text position retrieval to better cope with Tesseract’s glyphless font. Implements #803.

- **Added** an option to choose the prefix of new annotations, fields and links for providing unique annotation ids. Implements request #807.

- **Added** getting and setting color and text properties for Table of Contents items for PDFs. Implements #779.

- **Added** PDF page label handling: `Page.get_label()` returns the page label, `Document.get_page_numbers()` return all page numbers having a specified label, and `Document.set_page_labels()` adds or updates a PDF’s page label definition.

**Note:** This version introduces **Python type hinting**. The goal is to provide each parameter and the return value of all functions and methods with type information. This still is work in progress although the majority of functions has already been handled.

### 16.4 Changes in Version 1.18.5

Apart from several fixes, this version also focusses on several minor, but important feature improvements. Among the latter is a more precise computation of proper line heights and insertion points for writing / inserting text. As opposed to using font-agnostic constants, these values are now taken from the font’s properties.

Also note that this is the first version which does no longer provide pregenerated wheels for Python versions older than 3.6. PIP also discontinues support for these by end of this year 2020.

- **Fixed** issue #771. By using “small glyph heights” option, the full page text can be extracted.
• **Fixed** issue #768.
• **Fixed** issue #750.
• **Fixed** issue #739. The “dict”, “rawdict” and corresponding JSON output variants now have two new span keys: "ascender" and "descender". These floats represent special font properties which can be used to compute bboxes of spans or characters of exactly fontsize height (as opposed to the default line height). An example algorithm is shown in section “Span Dictionary” here. Also improved the detection and correction of ill-specified ascender / descender values encountered in some fonts.
• **Added** a new, experimental `Tools.set_small_glyph_heights()` – also in response to issue #739. This method sets or unsets a global parameter to always compute bboxes with fontsize height. If “on”, text searching and all text extractions will returned rectangles, bboxes and quads with a smaller height.
• **Fixed** issue #728.
• **Changed** fill color logic of ‘Polyline’ annotations: this parameter now only pertains to line end symbols – the annotation itself can no longer have a fill color. Also addresses issue #727.
• **Added** `Page.getImageBbox()` to also compute the bbox if the image is contained in an XObject.
• **Changed** `Shape.insertTextbox()`, `Page.insertTextbox()`, `TextWriter.fillTextbox()` to respect font’s properties “ascender” / “descender” when computing line height and insertion point. This should no longer lead to line overlaps for multi-line output. These methods used to ignore font specifics and used constant values instead.

### 16.5 Changes in Version 1.18.4

This version adds several features to support PDF Optional Content. Among other things, this includes OCMDs (Optional Content Membership Dictionaries) with the full scope of “visibility expressions” (PDF key /VE), text insertions (including the `TextWriter` class) and drawings.

• **Fixed** issue #727. Freetext annotations now support an uncolored rectangle when `fill_color=None`.
• **Fixed** issue #726. UTF-8 encoding errors are now handled for HTML / XML `Page.getText()` output.
• **Fixed** issue #724. Empty values are no longer stored in the PDF /Info metadata dictionary.
• **Added** new methods `Document.set_oc()` and `Document.get_oc()` to set or get optional content references for existing image and form XObjects. These methods are similar to the same-named methods of `Annot`.
• **Added** `Document.set_ocmd()`, `Document.get_ocmd()` for handling OCMDs.
• **Optional Content** support for text insertion and drawing.
• **Added** new method `Page.deleteWidget()`, which deletes a form field from a page. This is analogous to deleting annotations.
• **Added** support for Popup annotations. This includes defining the Popup rectangle and setting the Popup to open or closed. Methods / attributes `Annot.set_popup()`, `Annot.set_open()`, `Annot.has_popup`, `Annot.is_open`, `Annot.popup_rect`, `Annot.popup_xref`.

Other changes:

• The **naming of methods and attributes** in PyMuPDF is far from being satisfactory: we have *CamelCases*, *mixedCases* and *lower_case_with_underscores* all over the place. With the `Annot` as the first candidate, we have started an activity to clean this up step by step, converting to lower case with underscores for methods and attributes while keeping UPPERCASE for the constants.
  – Old names will remain available to prevent code breaks, but they will no longer be mentioned in the documentation.
– New methods and attributes of all classes will be named according to the new standard.

16.6 Changes in Version 1.18.3

As a major new feature, this version introduces support for PDF’s Optional Content concept.

• Fixed issue #714.
• Fixed issue #711.
• Fixed issue #707: if a PDF user password, but no owner password is supplied nor present, then the user password is also used as the owner password.
• Fixed expand and deflate parameters of methods Document.save() and Document.write(). Individual image and font compression should now finally work. Addresses issue #713.
• Added a support of PDF optional content. This includes several new Document methods for inquiring and setting optional content status and adding optional content configurations and groups. In addition, images, form XObjects and annotations now can be bound to optional content specifications. Resolved issue #709.

16.7 Changes in Version 1.18.2

This version contains some interesting improvements for text searching: any number of search hits is now returned and the hit_max parameter was removed. The new clip parameter in addition allows to restrict the search area. Searching now detects hyphenations at line breaks and accordingly finds hyphenated words.

• Fixed issue #575: if using quads=False in text searching, then overlapping rectangles on the same line are joined. Previously, parts of the search string, which belonged to different “marked content” items, each generated their own rectangle – just as if occurring on separate lines.
• Added Document.isRepaired, which is true if the PDF was repaired on open.
• Added Document.setXmlMetadata() which either updates or creates PDF XML metadata. Implements issue #691.
• Added Document.getXmlMetadata() returns PDF XML metadata.
• Changed creation of PDF documents: they will now always carry a PDF identification (/ID field) in the document trailer. Implements issue #691.
• Changed Page.searchFor(): a new parameter clip is accepted to restrict the search to this rectangle. Correspondingly, the attribute TextPage.rect is now respected by TextPage.search().
• Changed parameter hit_max in Page.searchFor() and TextPage.search() is now obsolete: methods will return all hits.
• Changed character selection criteria in Page.getText(): a character is now considered to be part of a clip if its bbox is fully contained. Before this, a non-empty intersection was sufficient.
• Changed Document.scrub() to support a new option redact_images. This addresses issue #697.

16.8 Changes in Version 1.18.1

• Fixed issue #692. PyMuPDF now detects and recovers from more cyclic resource dependencies in PDF pages and for the first time reports them in the MuPDF warnings store.
• **Fixed** issue #686.

• **Added** opacity options for the Shape class: Stroke and fill colors can now be set to some transparency value. This means that all Page draw methods, methods `Page.insertText()`, `Page.insertTextbox()`, `Shape.finish()`, `Shape.insertText()`, and `Shape.insertTextbox()` support two new parameters: `stroke_opacity` and `fill_opacity`.

• **Added** new parameter `mask` to `Page.insertImage()` for optionally providing an external image mask. Resolves issue #685.

• **Added** `Annot.soundGet()` for extracting the sound of an audio annotation.

**16.9 Changes in Version 1.18.0**

This is the first PyMuPDF version supporting MuPDF v1.18. The focus here is on extending PyMuPDF’s own functionality – apart from bug fixing. Subsequent PyMuPDF patches may address features new in MuPDF.

• **Fixed** issue #519. This upstream bug occurred occasionally for some pages only and seems to be fixed now: page layout should no longer be ruined in these cases.

• **Fixed** issue #675.
  – Unsuccessful storage allocations should now always lead to exceptions (circumvention of an upstream bug intermittently crashing the interpreter).
  – Pixmap size is now based on `size_t` instead of `int` in C and should be correct even for extremely large pixmaps.

• **Fixed** issue #668. Specification of dashes for PDF drawing insertion should now correctly reflect the PDF spec.

• **Fixed** issue #669. A major source of memory leakage in `Page.insert_pdf()` has been removed.

• **Added** keyword “images” to `Page.apply_redactions()` for fine-controlling the handling of images.

• **Added** `Annot.getText()` and `Annot.getTextbox()`, which offer the same functionality as the `Page` versions.

• **Added** key “number” to the block dictionaries of `Page.getText()` / `Annot.getText()` for options “dict” and “rawdict”.

• **Added** `glyph_name_to_unicode()` and `unicode_to_glyph_name()`. Both functions do not really connect to a specific font and are now independently available, too. The data are now based on the Adobe Glyph List.

• **Added** convenience functions `adobe_glyph_names()` and `adobe_glyph unicodes()` which return the respective available data.

• **Added** `Page.getDrawings()` which returns details of drawing operations on a document page. Works for all document types.

• **Improved** performance of `Document.insert_pdf()`. Multiple object copies are now also suppressed across multiple separate insertions from the same source. This saves time, memory and target file size. Previously this mechanism was only active within each single method execution. The feature can also be suppressed with the new method bool parameter `final=1`, which is the default.

• For PNG images created from pixmaps, the resolution (dpi) is now automatically set from the respective `Pixmap.xres` and `Pixmap.yres` values.
16.10 Changes in Version 1.17.7

- **Fixed** issue #651. An upstream bug causing interpreter crashes in corner case redaction processings was fixed by backporting MuPDF changes from their development repo.

- **Fixed** issue #645. Pixmap top-left coordinates can be set (again) by their own method, `Pixmap.setOrigin()`.

- **Fixed** issue #622. `Page.insertImage()` again accepts a `rect_like` parameter.

- **Added** several new methods to improve and speed-up table of contents (TOC) handling. Among other things, TOC items can now changed or deleted individually – without always replacing the complete TOC. Furthermore, access to some PDF page attributes is now possible without first loading the page. This has a very significant impact on the performance of TOC manipulation.

- **Added** an option to `Document.insert_pdf()` which allows displaying progress messages. Addresses #640.

- **Added** `Page.getTextbox()` which extracts text contained in a rectangle. In many cases, this should obsolete writing your own script for this type of thing.

- **Added** new `clip` parameter to `Page.getText()` to simplify and speed up text extraction of page sub areas.

- **Added** `TextWriter.appendv()` to add text in vertical write mode. Addresses issue #653

16.11 Changes in Version 1.17.6

- **Fixed** issue #605

- **Fixed** issue #600 – text should now be correctly positioned also for pages with a CropBox smaller than MediaBox.

- **Added** text span dictionary key `origin` which contains the lower left coordinate of the first character in that span.

- **Added** attribute `Font.buffer`, a `bytes` copy of the font file.

- **Added** parameter `sanitize` to `Page.cleanContents()`. Allows switching of sanitization, so only syntax cleaning will be done.

16.12 Changes in Version 1.17.5

- **Fixed** issue #561 – second go: certain `TextWriter` usages with many alternating fonts did not work correctly.

- **Fixed** issue #566.

- **Fixed** issue #568.

- **Fixed** – opacity is now correctly taken from the `TextWriter` object, if not given in `TextWriter.writeText()`.

- **Added** a new global attribute `fitz_fontdescriptors`. Contains information about usable fonts from repository pymupdf-fonts.

- **Added** `Font.valid_codepoints()` which returns an array of unicode codepoints for which the font has a glyph.

- **Added** option `text_as_path` to `Page.getSVGimage()` which implements #580. Generates much smaller SVG files with parseable text if set to `False`. 
16.13 Changes in Version 1.17.4

- **Fixed** issue #561. Handling of more than 10 *Font* objects on one page should now work correctly.
- **Fixed** issue #562. Annotation pixmaps are no longer derived from the page pixmap, thus avoiding unintended inclusion of page content.
- **Fixed** issue #559. This *MuPDF* bug is being temporarily fixed with a pre-version of *MuPDF*’s next release.
- **Added** utility function `repair_mono_font()` for correcting displayed character spacing for some mono-spaced fonts.
- **Added** utility method `Document.needAppearances()` for fine-controlling Form PDF behavior. Addresses issue #563.
- **Added** utility function `sRGB_to_pdf()` to recover the PDF color triple for a given color integer in sRGB format.
- **Added** utility function `sRGB_to_rgb()` to recover the (R, G, B) color triple for a given color integer in sRGB format.
- **Added** utility function `make_table()` which delivers table cells for a given rectangle and desired numbers of columns and rows.
- **Added** support for optional fonts in repository *pymupdf-fonts*.

16.14 Changes in Version 1.17.3

- **Fixed** an undocumented issue, which prevented fully cleaning a PDF page when using `Page.cleanContents()`.
- **Fixed** issue #540. Text extraction for EPUB should again work correctly.
- **Fixed** issue #548. Documentation now includes `LINK_NAMED`.
- **Added** new parameter to control start of text in `TextWriter.fillTextbox()`. Implements #549.
- **Changed** documentation of `Page.addRedactAnnot()` to explain the usage of non-built-in fonts.

16.15 Changes in Version 1.17.2

- **Fixed** issue #533.
- **Added** options to modify ‘Redact’ annotation appearance. Implements #535.

16.16 Changes in Version 1.17.1

- **Fixed** issue #520.
- **Fixed** issue #525. Vertices for ‘Ink’ annots should now be correct.
- **Fixed** issue #524. It is now possible to query and set rotation for applicable annotation types.

Also significantly improved inline documentation for better support of interactive help.
16.17 Changes in Version 1.17.0

This version is based on MuPDF v1.17. Following are highlights of new and changed features:

- **Added** extended language support for annotations and widgets: a mixture of Latin, Greece, Russian, Chinese, Japanese and Korean characters can now be used in ‘FreeText’ annotations and text widgets. No special arrangement is required to use it.

- Faster page access is implemented for documents supporting a “chapter” structure. This applies to EPUB documents currently. This comes with several new Document methods and changes for Document.loadPage() and the “indexed” page access doc[n]: In addition to specifying a page number as before, a tuple (chapter, pno) can be specified to identify the desired page.

- **Changed:** Improved support of redaction annotations: images overlapped by redactions are permanently modified by erasing the overlap areas. Also links are removed if overlapped by redactions. This is now fully in sync with PDF specifications.

Other changes:

- **Changed** TextWriter.writeText() to support the “morph” parameter.

- **Added** methods Rect.morph(), IRect.morph(), and Quad.morph(), which return a new Quad.

- **Changed** Page.addFreetextAnnot() to support text alignment via a new “align” parameter.

- **Fixed** issue #508. Improved image rectangle calculation to hopefully deliver correct values in most if not all cases.

- **Fixed** issue #502.

- **Fixed** issue #500. Document.convertToPDF() should no longer cause memory leaks.

- **Fixed** issue #496. Annotations and widgets / fields are now added or modified using the coordinates of the unrotated page. This behavior is now in sync with other methods modifying PDF pages.

- **Added** Page.rotationMatrix and Page.derotationMatrix to support coordinate transformations between the rotated and the original versions of a PDF page.

Potential code breaking changes:

- The private method Page._getTransformation() has been removed. Use the public Page.transformationMatrix instead.

16.18 Changes in Version 1.16.18

This version introduces several new features around PDF text output. The motivation is to simplify this task, while at the same time offering extending features.

One major achievement is using MuPDF’s capabilities to dynamically choosing fallback fonts whenever a character cannot be found in the current one. This seamlessly works for Base-14 fonts in combination with CJK fonts (China, Japan, Korea). So a text may contain any combination of characters from the Latin, Greek, Russian, Chinese, Japanese and Korean languages.

- **Fixed** issue #493. Fixmap(doc, xref) should now again correctly resemble the loaded image object.

- **Fixed** issue #488. Widget names are now modifiable.

- **Added** new class Font which represents a font.

- **Added** new class TextWriter which serves as a container for text to be written on a page.

- **Added** Page.writeText() to write one or more TextWriter objects to the page.
16.19 Changes in Version 1.16.17

- **Fixed** issue #479. PyMuPDF should now more correctly report image resolutions. This applies to both, images (either from images files or extracted from PDF documents) and pixmaps created from images.
- **Added** `Pixmap.setResolution()` which sets the image resolution in x and y directions.

16.20 Changes in Version 1.16.16

- **Fixed** issue #477.
- **Fixed** issue #476.
- **Changed** annotation line end symbol coloring and fixed an error coloring the interior of ‘Polyline’ /’Polygon’ annotations.

16.21 Changes in Version 1.16.14

- **Changed** text marker annotations to accept parameters beyond just quadrilaterals such that now text lines between two given points can be marked.
- **Added** `Document.scrub()` which removes potentially sensitive data from a PDF. Implements #453.
- **Added** `Annot.blendMode()` which returns the blend mode of annotations.
- **Added** `Annot.setBlendMode()` to set the annotation’s blend mode. This resolves issue #416.
- **Changed** `Annot.update()` to accept additional parameters for setting blend mode and opacity.
- **Added** advanced graphics features to control the anti-aliasing values, `Tools.set_aa_level()`. Resolves #467
- **Fixed** issue #474.
- **Fixed** issue #466.

16.22 Changes in Version 1.16.13

- **Added** `Document.getPageXObjectList()` which returns a list of Form XObjects of the page.
- **Added** `Page.setMediaBox()` for changing the physical PDF page size.
- **Added** `Page` methods which have been internal before: `Page.cleanContents()` (= `Page._cleanContents()`), `Page.getContents()` (= `Page._getContents()`), `Page.getTransformation()` (= `Page._getTransformation()`).

16.23 Changes in Version 1.16.12

- **Fixed** issue #447
- **Fixed** issue #461.
- **Fixed** issue #397.
• Fixed issue #463.
• Added JavaScript support to PDF form fields, thereby fixing #454.
• Added a new annotation method `Annot.delete_responses()`, which removes ‘Popup’ and response annotations referring to the current one. Mainly serves data protection purposes.
• Added a new form field method `Widget.reset()`, which resets the field value to its default.
• Changed and extended handling of redactions: images and XObjects are removed if contained in a redaction rectangle. Any partial only overlaps will just be covered by the redaction background color. Now an overlay text can be specified to be inserted in the rectangle area to take the place the deleted original text. This resolves #434.

16.24 Changes in Version 1.16.11

• Added Support for redaction annotations via method `Page.addRedactAnnot()` and `Page.apply_redactions()`.
• Fixed issue #426 (“PolygonAnnotation in 1.16.10 version”).
• Fixed documentation only issues #443 and #444.

16.25 Changes in Version 1.16.10

• Fixed issue #421 (“annot.setRect(rect) has no effect on text Annotation’)
• Fixed issue #417 (“Strange behavior for page.deleteAnnot on 1.16.9 compare to 1.13.20”)
• Fixed issue #415 (“Annot.setOpacity throws mupdf warnings”)
• Changed all “add annotation / widget” methods to store a unique name in the /NM PDF key.
• Changed `Annot.setInfo()` to also accept direct parameters in addition to a dictionary.
• Changed `Annot.info` to now also show the annotation’s unique id (/NM PDF key) if present.
• Added `Page.annot_names()` which returns a list of all annotation names (/NM keys).
• Added `Page.load_annot()` which loads an annotation given its unique id (/NM key).
• Added `Document.reload_page()` which provides a new copy of a page after finishing any pending updates to it.

16.26 Changes in Version 1.16.9

• Fixed #412 (“Feature Request: Allow controlling whether TOC entries should be collapsed”)
• Fixed #411 (“Seg Fault with page.firstWidget”)
• Fixed #407 (“Annot.setOpacity trouble”)
• Changed methods `Annot.setBorder()`, `Annot.setColors()`, `Link.setBorder()`, and `Link.setColors()` to also accept direct parameters, and not just cumbersome dictionaries.
16.27 Changes in Version 1.16.8

- **Added** several new methods to the `Document` class, which make dealing with PDF low-level structures easier. I also decided to provide them as “normal” methods (as opposed to private ones starting with an underscore “_”). These are `Document.xrefObject()`, `Document.xrefStream()`, `Document.xrefStreamRaw()`, `Document.PDFTrailer()`, `Document.PDFCatalog()`, `Document.metadataXML()`, `Document.updateObject()`, `Document.updateStream()`.

- **Added** `Tools.mupdf_disply_errors()` which sets the display of mupdf errors on `sys.stderr`.

- **Added** a commandline facility. This a major new feature: you can now invoke several utility functions via "`python -m fitz ...`". It should obsolete the need for many of the most trivial scripts. Please refer to Using fitz as a Module.

16.28 Changes in Version 1.16.7

Minor changes to better synchronize the binary image streams of `TextPage` image blocks and `Document.extractImage()` images.

- **Fixed** issue #394 (“PyMuPDF Segfaults when using TOOLS.mupdf_warnings()”).

- **Changed** redirection of MuPDF error messages: apart from writing them to Python `sys.stderr`, they are now also stored with the MuPDF warnings.

- **Changed** `Tools.mupdf_warnings()` to automatically empty the store (if not deactivated via a parameter).

- **Changed** `Page.getImageBbox()` to return an infinite rectangle if the image could not be located on the page – instead of raising an exception.

16.29 Changes in Version 1.16.6

- **Fixed** issue #390 (“Incomplete deletion of annotations”).

- **Changed** `Page.searchFor()` / `Document.searchPageFor()` to also support the `flags` parameter, which controls the data included in a `TextPage`.

- **Changed** `Document.getPageImageList()`, `Document.getPageFontList()` and their `Page` counterparts to support a new parameter `full`. If true, the returned items will contain the `xref` of the `Form XObject` where the font or image is referenced.

16.30 Changes in Version 1.16.5

More performance improvements for text extraction.

- **Fixed** second part of issue #381 (see item in v1.16.4).

- **Added** `Page.getTextPage()`, so it is no longer required to create an intermediate display list for text extractions. Page level wrappers for text extraction and text searching are now based on this, which should improve performance by ca. 5%.
16.31 Changes in Version 1.16.4

- **Fixed** issue #381 ("TextPage.extractDICT ... failed ... after upgrading ... to 1.16.3")
- **Added** method `Document.pages()` which delivers a generator iterator over a page range.
- **Added** method `Page.links()` which delivers a generator iterator over the links of a page.
- **Added** method `Page.annots()` which delivers a generator iterator over the annotations of a page.
- **Added** method `Page.widgets()` which delivers a generator iterator over the form fields of a page.
- **Changed** `Document.is_form_pdf` to now contain the number of widgets, and `False` if not a PDF or this number is zero.

16.32 Changes in Version 1.16.3

Minor changes compared to version 1.16.2. The code of the “dict” and “rawdict” variants of `Page.getText()` has been ported to C which has greatly improved their performance. This improvement is mostly noticeable with text-oriented documents, where they now should execute almost two times faster.

- **Fixed** issue #369 ("mupdf: cmsCreateTransform failed") by removing ICC colorspace support.
- **Changed** `Page.getText()` to accept additional keywords “blocks” and “words”. These will deliver the results of `Page.getTextBlocks()` and `Page.getTextWords()`, respectively. So all text extraction methods are now available via a uniform API. Correspondingly, there are now new methods `TextPage.extractBLOCKS()` and `TextPage.extractWords()`.
- **Changed** `Page.getText()` to default bit indicator `TEXT_INHIBIT_SPACES` to `off`. Insertion of additional spaces is **not suppressed** by default.

16.33 Changes in Version 1.16.2

- **Changed** text extraction methods of `Page` to allow detail control of the amount of extracted data.
- **Added** `planishLine()` which maps a given line (defined as a pair of points) to the x-axis.
- **Fixed** an issue (w/o Github number) which brought down the interpreter when encountering certain non-UTF-8 encodable characters while using `Page.getText()` with te “dict” option.
- **Fixed** issue #362 (“Memory Leak with getText(‘rawDICT’)”).

16.34 Changes in Version 1.16.1

- **Added** property `Quad.isConvex` which checks whether a line is contained in the quad if it connects two points of it.
- **Changed** `Document.insert_pdf()` to now allow dropping or including links and annotations independently during the copy. Fixes issue #352 (“Corrupt PDF data and ...”), which seemed to intermittently occur when using the method for some problematic PDF files.
- **Fixed** a bug which, in matrix division using the syntax “m1/m2”, caused matrix “m1” to be replaced by the result instead of delivering a new matrix.
• Fixed issue #354 (“SyntaxWarning with Python 3.8”). We now always use “==” for literals (instead of the “is” Python keyword).
• Fixed issue #353 (“mupdf version check”), to no longer refuse the import when there are only patch level deviations from MuPDF.

16.35 Changes in Version 1.16.0

This major new version of MuPDF comes with several nice new or changed features. Some of them imply programming API changes, however. This is a synopsis of what has changed:

• PDF document encryption and decryption is now fully supported. This includes setting permissions, passwords (user and owner passwords) and the desired encryption method.

• In response to the new encryption features, PyMuPDF returns an integer (i.e. a combination of bits) for document permissions, and no longer a dictionary.

• Redirection of MuPDF errors and warnings is now natively supported. PyMuPDF redirects error messages from MuPDF to sys.stderr and no longer buffers them. Warnings continue to be buffered and will not be displayed. Functions exist to access and reset the warnings buffer.

• Annotations are now only supported for PDF.

• Annotations and widgets (form fields) are now separate object chains on a page (although widgets technically still are PDF annotations). This means, that you will never encounter widgets when using Page.firstAnnot or Annot.next(). You must use Page.firstWidget and Widget.next() to access form fields.

• As part of MuPDF’s changes regarding widgets, only the following four fonts are supported, when adding or changing form fields: Courier, Helvetica, Times-Roman and ZapfDingBats.

List of change details:

• Added Document.can_save_incrementally() which checks conditions that are preventing use of option incremental=True of Document.save().
• Added Page.firstWidget which points to the first field on a page.
• Added Page.getImageBbox() which returns the rectangle occupied by an image shown on the page.
• Added Annot.setName() which lets you change the (icon) name field.
• Added outputting the text color in Page.getText(): the “dict”, “rawdict” and “xml” options now also show the color in sRGB format.
• Changed Document.permissions to now contain an integer of bool indicators – was a dictionary before.
• Changed Document.save(), Document.write(), which now fully support password-based decryption and encryption of PDF files.
• Changed the names of all Python constants related to annotations and widgets. Please make sure to consult the Constants and Enumerations chapter if your script is dealing with these two classes. This decision goes back to the dropped support for non-PDF annotations. The old names (starting with “ANNOT_*” or “WIDGET_*”) will be available as deprecated synonyms.
• Changed font support for widgets: only Cour (Courier), Helv (Helvetica, default), TiRo (Times-Roman) and ZaDb (ZapfDingBats) are accepted when adding or changing form fields. Only the plain versions are possible – not their italic or bold variations. Reading widgets, however will show its original font.
• Changed the name of the warnings buffer to Tools.mupdf_warnings() and the function to empty this buffer is now called Tools.reset_mupdf_warnings().
• Changed `Page.getPixmap()`, `Document.get_page_pixmap()`; a new bool argument `annots` can now be used to suppress the rendering of annotations on the page.

• Changed `Page.addFileAnnot()` and `Page.addTextAnnot()` to enable setting an icon.

• Removed widget-related methods and attributes from the `Annot` object.

• Removed `Document` attributes `openErrCode`, `openErrMsg`, and `Tools` attributes / methods `stderr`, `reset_stderr`, `stdout`, and `reset_stdout`.

• Removed thirdparty `zlib` dependency in PyMuPDF: there are now compression functions available in MuPDF. Source installers of PyMuPDF may now omit this extra installation step.

16.36 No version published for MuPDF v1.15.0

• Changed text marker annotations to support multiple rectangles / quadrilaterals. This fixes issue #341 (“Question: How to add highlight so that a string spread across more than a line is covered by one highlight?”) and similar (#285).

• Fixed issue #331 (“Importing PyMuPDF changes warning filtering behaviour globally”).

• Fixed issue #319 (“InsertText function error when use custom font”).

• Added new method `Document.get_sigflags()` which returns information on whether a PDF is signed. Resolves issue #326 (“How to detect signature in a form pdf?”).

• Added `Document.fullcopyPage()` to make full page copies within a PDF (not just copied references as `Document.copyPage()` does).

• Changed `Page.getPixmap()`, `Document.get_page_pixmap()` now use `alpha=False` as default.

• Changed text extraction: the span dictionary now (again) contains its rectangle under the `bbox` key.

• Changed `Document` methods around PDF `/EmbeddedFiles` to no longer use MuPDF’s “portfolio” functions. That support will be dropped in MuPDF v1.15 – therefore another solution was required.

• Changed `Document.embfile_Count()` to be a function (was an attribute).

• Added new method `Document.embfile_Names()` which returns a list of names of embedded files.
• **Changed** `Document.delete_page()` and `Document.delete_pages()` to internally no longer use `Document.select()`, but instead use functions to perform the deletion directly. As it has turned out, the `Document.select()` method yields invalid outline trees (tables of content) for very complex PDFs and sophisticated use of annotations.

### 16.41 Changes in Version 1.14.15

• **Fixed** issues #301 (“Line cap and Line join”), #300 (“How to draw a shape without outlines”) and #298 (“utils.updateRect exception”). These bugs pertain to drawing shapes with PyMuPDF. Drawing shapes without any border is fully supported. Line cap styles and line line join style are now differentiated and support all possible PDF values (0, 1, 2) instead of just being a bool. The previous parameter `roundCap` is deprecated in favor of `lineCap` and `lineJoin` and will be deleted in the next release.

• **Fixed** issue #290 (“Memory Leak with getText(‘rawDICT’)”). This bug caused memory not being (completely) freed after invoking the “dict”, “rawdict” and “json” versions of `Page.getText()`.

• **Added** new low-level function `ImageProperties()` to determine a number of characteristics for an image.

• **Added** new low-level function `Document.is_stream()`, which checks whether an object is of stream type.

• **Changed** low-level functions `Document._getXrefString()` and `Document._getTrailerString()` now by default return object definitions in a formatted form which makes parsing easy.

• **Changed** methods working with binary input: while ever supporting bytes and bytearray objects, they now also accept `io.BytesIO` input, using their `getvalue()` method. This pertains to document creation, embedded files, FileAttachment annotations, pixmap creation and others. Fixes issue #274 (“Segfault when using BytesIO as a stream for insertImage”).

• **Fixed** issue #278 (“Is insertImage(keep_proportion=True) broken?”). Images are now correctly presented when keeping aspect ratio.

• **Changed** the draw methods of `Page` and `Shape` to support not only RGB, but also GRAY and CMYK colorspace. This solves issue #270 (“Is there a way to use CMYK color to draw shapes?”). This change also applies to text insertion methods of `Shape`, resp. `Page`.

• **Fixed** issue #269 (“AttributeError in Document.insert_page()”), which occurred when using `Document.insert_page()` with text insertion.

- **Changed** `Page.show_pdf_page()` to always position the source rectangle centered in the target. This method now also supports rotation by arbitrary angles. The argument `reuse_xref` has been deprecated: prevention of duplicates is now handled internally.

- **Changed** `Page.insertImage()` to support rotated display of the image and keeping the aspect ratio. Only rotations by multiples of 90 degrees are supported here.

- **Fixed** issue #265 (“TypeError: insertText() got an unexpected keyword argument ‘idx’”). This issue only occurred when using `Document.insert_page()` with also inserting text.

16.46 Changes in Version 1.14.10

- **Changed** `Page.show_pdf_page()` to support rotation of the source rectangle. Fixes #261 (“Cannot rotate inserted pages”).

- **Fixed** a bug in `Page.insertImage()` which prevented insertion of multiple images provided as streams.

- **Added** new low-level method `Document._getTrailerString()`, which returns the trailer object of a PDF. This is much like `Document._getXrefString()` except that the PDF trailer has no / needs no `xref` to identify it.

- **Added** new parameters for text insertion methods. You can now set stroke and fill colors of glyphs (text characters) independently, as well as the thickness of the glyph border. A new parameter `render_mode` controls the use of these colors, and whether the text should be visible at all.

- **Fixed** issue #258 (“Copying image streams to new PDF without size increase”): For JPX images embedded in a PDF, `Document.extractImage()` will now return them in their original format. Previously, the MuPDF base library was used, which returns them in PNG format (entailing a massive size increase).

- **Fixed** issue #259 (“Morphing text to fit inside rect”). Clarified use of `getTextlength()` and removed extra line breaks for long words.

16.48 Changes in Version 1.14.8

- **Added** `Pixmap.setRect()` to change the pixel values in a rectangle. This is also an alternative to setting the color of a complete pixmap (`Pixmap.clearWith()`).

- **Fixed** an image extraction issue with JBIG2 (monochrome) encoded PDF images. The issue occurred in `Page.getText()` (parameters “dict” and “rawdict”) and in `Document.extractImage()` methods.

- **Fixed** an issue with not correctly clearing a non-alpha `Pixmap` (`Pixmap.clearWith()`).

- **Fixed** an issue with not correctly inverting colors of a non-alpha `Pixmap` (`Pixmap.invertIRect()`).

- **Added** `Pixmap.setPixel()` to change one pixel value.
PyMuPDF Documentation, Release 1.18.8

- **Added** documentation for image conversion in the *Collection of Recipes*.
- **Added** new function `getTextlength()` to determine the string length for a given font.
- **Added** Postscript image output (changed `Pixmap.writeImage()` and `Pixmap.getImageData()`).
- **Changed** `Pixmap.writeImage()` and `Pixmap.getImageData()` to ensure valid combinations of colorspace, alpha and output format.
- **Changed** `Pixmap.writeImage()`: the desired format is now inferred from the filename.
- **Changed** FreeText annotations can now have a transparent background - see `Annot.update()`.

### 16.50 Changes in Version 1.14.5

- **Changed**: `Shape` methods now strictly use the transformation matrix of the `Page` – instead of “manually” calculating locations.
- **Added** method `Pixmap.pixel()` which returns the pixel value (a list) for given pixel coordinates.
- **Added** method `Pixmap.getImageData()` which returns a bytes object representing the pixmap in a variety of formats. Previously, this could be done for PNG outputs only (`Pixmap.getPNGData()`).
- **Changed**: output of methods `Pixmap.writeImage()` and (the new) `Pixmap.getImageData()` may now also be PSD (Adobe Photoshop Document).
- **Added** method `Shape.drawQuad()` which draws a `Quad`. This actually is a shorthand for a `Shape.drawPolyline()` with the edges of the quad.
- **Changed** method `Shape.drawOval()`: the argument can now be either a rectangle (`rect_like`) or a quadrilateral (`quad_like`).

### 16.51 Changes in Version 1.14.4

- **Fixes** issue #239 “Annotation coordinate consistency”.

### 16.52 Changes in Version 1.14.3

This patch version contains minor bug fixes and CJK font output support.

- **Added** support for the four CJK fonts as PyMuPDF generated text output. This pertains to methods `Page.insertFont()`, `Shape.insertText()`, `Shape.insertTextbox()`, and corresponding `Page` methods. The new fonts are available under “reserved” fontnames “china-t” (traditional Chinese), “china-s” (simplified Chinese), “japan” (Japanese), and “korea” (Korean).
- **Added** full support for the built-in fonts ‘Symbol’ and ‘Zapfdingbats’.
- **Changed**: The 14 standard fonts can now each be referenced by a 4-letter abbreviation.

### 16.53 Changes in Version 1.14.1

This patch version contains minor performance improvements.

- **Added** support for `Document` filenames given as `pathlib` object by using the Python `str()` function.
16.54 Changes in Version 1.14.0

To support MuPDF v1.14.0, massive changes were required in PyMuPDF – most of them purely technical, with little visibility to developers. But there are also quite a lot of interesting new and improved features. Following are the details:

- **Added** “ink” annotation.
- **Added** “rubber stamp” annotation.
- **Added** “squiggly” text marker annotation.
- **Added** new class Quad (quadrilateral or tetragon) – which represents a general four-sided shape in the plane. The special subtype of rectangular, non-empty tetragons is used in text marker annotations and as returned objects in text search methods.
- **Added** a new option “decrypt” to Document.save() and Document.write(). Now you can keep encryption when saving a password protected PDF.
- **Added** suppression and redirection of unsolicited messages issued by the underlying C-library MuPDF. Consult Redirecting Error and Warning Messages for details.
- **Changed**: Changes to annotations now **always require** Annot.update() to become effective.
- **Changed** free text annotations to support the full Latin character set and range of appearance options.
- **Changed** text searching, Page.searchFor(), to optionally return Quad instead Rect objects surrounding each search hit.
- **Changed** plain text output: we now add a n to each line if it does not itself end with this character.
- **Fixed** issue 211 (“Something wrong in the doc”).
- **Fixed** issue 213 (“Rewritten outline is displayed only by mupdf-based applications”).
- **Fixed** issue 214 (“PDF decryption GONE!”).
- **Fixed** issue 215 (“Formatting of links added with pyMuPDF”).
- **Fixed** issue 217 (“extraction through json is failing for my pdf”).

Behind the curtain, we have changed the implementation of geometry objects: they now purely exist in Python and no longer have “shadow” twins on the C-level (in MuPDF). This has improved processing speed in that area by more than a factor of two.

Because of the same reason, most methods involving geometry parameters now also accept the corresponding Python sequence. For example, in method “page.show_pdf_page(rect, ...)” parameter rect may now be any rect_like sequence.

We also invested considerable effort to further extend and improve the Collection of Recipes chapter.

16.55 Changes in Version 1.13.19

This version contains some technical / performance improvements and bug fixes.

- **Changed** memory management: for Python 3 builds, Python memory management is exclusively used across all C-level code (i.e. no more native malloc() in MuPDF code or PyMuPDF interface code). This leads to improved memory usage profiles and also some runtime improvements: we have seen > 2% shorter runtimes for text extractions and pixmap creations (on Windows machines only to date).
- **Fixed** an error occurring in Python 2.7, which crashed the interpreter when using TextPage.extractRAWDICT() (= Page.getText(“rawdict”)).
• **Fixed** an error occurring in Python 2.7, when creating link destinations.
• **Extended** the *Collection of Recipes* chapter with more examples.

### 16.56 Changes in Version 1.13.18

• **Added** method `TextPage.extractRAWdict()`, and a corresponding new string parameter “rawdict” to method `Page.getText()`. It extracts text and images from a page in Python `dict` form like `TextPage.extractDICT()`, but with the detail level of `TextPage.extractXML()`, which is position information down to each single character.

### 16.57 Changes in Version 1.13.17

• **Fixed** an error that intermittently caused an exception in `Page.show_pdf_page()`, when pages from many different source PDFs were shown.
• **Changed** method `Document.extractImage()` to now return more meta information about the extracted image. Also, its performance has been greatly improved. Several demo scripts have been changed to make use of this method.
• **Changed** method `Document._getXrefStream()` to now return `None` if the object is no stream and no longer raise an exception if otherwise.
• **Added** method `Document._deleteObject()` which deletes a PDF object identified by its `xref`. Only to be used by the experienced PDF expert.
• **Added** a method `PaperRect()` which returns a `Rect` for a supplied paper format string. Example: `fitz.PaperRect("letter") = fitz.Rect(0.0, 0.0, 612.0, 792.0)`.
• **Added** a *Collection of Recipes* chapter to this document.

### 16.58 Changes in Version 1.13.16

• **Added** support for correctly setting transparency (opacity) for certain annotation types.
• **Added** a tool property `(Tools.fitz_config)` showing the configuration of this PyMuPDF version.
• **Fixed** issue #193 (‘insertText(overlay=False) gives “cannot resize a buffer with shared storage” error’) by avoiding read-only buffers.

### 16.59 Changes in Version 1.13.15

• **Fixed** issue #189 ("cannot find builtin CJK font"), so we are supporting builtin CJK fonts now (CJK = China, Japan, Korea). This should lead to correctly generated pixmaps for documents using these languages. This change has consequences for our binary file size: it will now range between 8 and 10 MB, depending on the OS.
• **Fixed** issue #191 ("Jupyter notebook kernel dies after ca. 40 pages"), which occurred when modifying the contents of an annotation.
16.60 Changes in Version 1.13.14

This patch version contains several improvements, mainly for annotations.

- **Changed** `Annot.lineEnds` is now a list of two integers representing the line end symbols. Previously was a `dict` of strings.

- **Added** support of line end symbols for applicable annotations. PyMuPDF now can generate these annotations including the line end symbols.

- **Added** `Annot.setLineEnds()` adds line end symbols to applicable annotation types (‘Line’, ‘PolyLine’, ‘Polygon’).

- **Changed** technical implementation of `Page.insertImage()` and `Page.show_pdf_page()`: they now create their own contents objects, thereby avoiding changes of potentially large streams with consequential compression/decompression efforts and high change volumes with incremental updates.

16.61 Changes in Version 1.13.13

This patch version contains several improvements for embedded files and file attachment annotations.

- **Added** `Document.embfile_Upd()` which allows changing file content and metadata of an embedded file. It supersedes the old method `Document.embfile_SetInfo()` (which will be deleted in a future version). Content is automatically compressed and metadata may be unicode.

- **Changed** `Document.embfile_Add()` to now automatically compress file content. Accompanying metadata can now be unicode (had to be ASCII in the past).

- **Changed** `Document.embfile_Del()` to now automatically delete all entries having the supplied identifying name. The return code is now an integer count of the removed entries (was `None` previously).

- **Added** `Page.addFileAnnot()` which adds a new file attachment annotation.

- **Changed** `Annot.fileUpd()` (file attachment annot) to now also accept the PDF unicode `ufilename` parameter. The description parameter `desc` correctly works with unicode. Furthermore, all parameters are optional, so metadata may be changed without also replacing the file content.

- **Changed** `Annot.fileInfo()` (file attachment annot) to now also show the PDF unicode filename as parameter `ufilename`.

- **Fixed** issue #180 (“page.getText(output=’dict’) return invalid bbox”) to now also work for vertical text.

- **Fixed** issue #185 (“Can’t render the annotations created by PyMuPDF”). The issue’s cause was the minimalistic MuPDF approach when creating annotations. Several annotation types have no `/AP` (“appearance”) object when created by MuPDF functions. MuPDF, SumatraPDF and hence also PyMuPDF cannot render annotations without such an object. This fix now ensures, that an appearance object is always created together with the annotation itself. We still do not support line end styles.

- **Fixed** issue #180 (“page.getText(output=’dict’) return invalid bbox”). Note that this is a circumvention of an MuPDF error, which generates zero-height character rectangles in some cases. When this happens, this fix ensures a bbox height of at least fontsize.
• **Changed** for ListBox and ComboBox widgets, the attribute list of selectable values has been renamed to `Widget.choice_values`.

• **Changed** when adding widgets, any missing of the PDF Base 14 Fonts is automatically added to the PDF. Widget text fonts can now also be chosen from existing widget fonts. Any specified field values are now honored and lead to a field with a preset value.

• **Added** `Annot.updateWidget()` which allows changing existing form fields – including the field value.

### 16.63 Changes in Version 1.13.11

While the preceeding patch subversions only contained various fixes, this version again introduces major new features:

• **Added** basic support for PDF widget annotations. You can now add PDF form fields of types Text, CheckBox, ListBox and ComboBox. Where necessary, the PDF is transformed to a Form PDF with the first added widget.

• **Fixed** issues #176 (“wrong file embedding”), #177 (“segment fault when invoking page.getText()”) and #179 (“Segmentation fault using page.getLinks() on encrypted PDF”).

### 16.64 Changes in Version 1.13.7

• **Added** support of variable page sizes for reflowable documents (e-books, HTML, etc.): new parameters `rect` and `fontsize` in `Document` creation (open), and as a separate method `Document.layout()`.

• **Added** `Annot` creation of many annotations types: sticky notes, free text, circle, rectangle, line, polygon, polyline and text markers.

• **Added** support of annotation transparency (`Annot.opacity`, `Annot.setOpacity()`).

• **Changed** `Annot.vertices`: point coordinates are now grouped as pairs of floats (no longer as separate floats).

• **Changed** annotation colors dictionary: the two keys are now named “stroke” (formerly “common”) and “fill”.

• **Added** `Document.isDirty` which is `True` if a PDF has been changed in this session. Reset to `False` on each `Document.save()` or `Document.write()`.

### 16.65 Changes in Version 1.13.6

• **Fix** #173: for memory-resident documents, ensure the stream object will not be garbage-collected by Python before document is closed.

### 16.66 Changes in Version 1.13.5

• New low-level method `Page._setContents()` defines an object given by its `xref` to serve as the `contents` object.

• **Changed** and extended PDF form field support: the attribute `widget.text` has been renamed to `Annot.widget_value`. Values of all form field types (except signatures) are now supported. A new attribute `Annot.widget_choices` contains the selectable values of listboxes and comboboxes. All these attributes now contain `None` if no value is present.
16.67 Changes in Version 1.13.4

- `Document.convertToPDF()` now supports page ranges, reverted page sequences and page rotation. If the document already is a PDF, an exception is raised.
- Fixed a bug (introduced with v1.13.0) that prevented `Page.insertImage()` for transparent images.

16.68 Changes in Version 1.13.3

Introduces a way to convert any MuPDF supported document to a PDF. If you ever wanted PDF versions of your XPS, EPUB, CBZ or FB2 files – here is a way to do this.

- `Document.convertToPDF()` returns a Python `bytes` object in PDF format. Can be opened like normal in PyMuPDF, or be written to disk with the “.pdf” extension.

16.69 Changes in Version 1.13.2

The major enhancement is PDF form field support. Form fields are annotations of type `(19, ‘Widget’)`. There is a new document method to check whether a PDF is a form. The `Annot` class has new properties describing field details.

- `Document.is_form_pdf` is true if object type `/AcroForm` and at least one form field exists.
- `Annot.widget_type`, `Annot.widget_text` and `Annot.widget_name` contain the details of a form field (i.e. a “Widget” annotation).

16.70 Changes in Version 1.13.1

- `TextPage.extractDICT()` is a new method to extract the contents of a document page (text and images). All document types are supported as with the other `TextPage extract*()` methods. The returned object is a dictionary of nested lists and other dictionaries, and exactly equal to the JSON-deserialization of the old `TextPage.extractJSON()`. The difference is that the result is created directly – no JSON module is used. Because the user needs no JSON module to interpret the information, it should be easier to use, and also have a better performance, because it contains images in their original binary format – they need not be base64-decoded.
- `Page.getText()` correspondingly supports the new parameter value “dict” to invoke the above method.
- `TextPage.extractJSON()` (resp. `Page.getText("json")`) is still supported for convenience, but its use is expected to decline.

16.71 Changes in Version 1.13.0

This version is based on MuPDF v1.13.0. This release is “primarily a bug fix release”.

In PyMuPDF, we are also doing some bug fixes while introducing minor enhancements. There only very minimal changes to the user’s API.

- `Document` construction is more flexible: the new `filetype` parameter allows setting the document type. If specified, any extension in the filename will be ignored. More completely addresses issue #156. As part of this, the documentation has been reworked.
• Changes to *Pixmap* constructors:
  – Colorspace conversion no longer allows dropping the alpha channel: source and target *alpha* will now always be the same. We have seen exceptions and even interpreter crashes when using *alpha = 0*.
  – As a replacement, the simple pixmap copy lets you choose the target alpha.

• *Document.save()* again offers the full garbage collection range 0 thru 4. Because of a bug in *xref* maintenance, we had to temporarily enforce *garbage > 1*. Finally resolves issue #148.

• *Document.save()* now offers to “prettify” PDF source via an additional argument.

• *Page.insertImage()* has the additional *stream*-parameter, specifying a memory area holding an image.

• Issue with garbled PNGs on Linux systems has been resolved (“Problem writing PNG” #133).

### 16.72 Changes in Version 1.12.4

This is an extension of 1.12.3.

• Fix of issue #147: methods *Document.getPageFontlist()* and *Document.getPageImagelist()* now also show fonts and images contained in *resources* nested via “Form XObjects”.

• Temporary fix of issue #148: Saving to new PDF files will now automatically use *garbage = 2* if a lower value is given. Final fix is to be expected with MuPDF’s next version. At that point we will remove this circumvention.

• Preventive fix of illegally using stencil / image mask pixmaps in some methods.

• Method *Document.getPageFontlist()* now includes the encoding name for each font in the list.

• Method *Document.getPageImagelist()* now includes the decode method name for each image in the list.

### 16.73 Changes in Version 1.12.3

This is an extension of 1.12.2.

• Many functions now return *None* instead of 0, if the result has no other meaning than just indicating successful execution (*Document.close()*), *Document.save()*), *Document.select()*), *Pixmap.writePNG()* and many others).

### 16.74 Changes in Version 1.12.2

This is an extension of 1.12.1.

• Method *Page.show_pdf_page()* now accepts the new *clip* argument. This specifies an area of the source page to which the display should be restricted.

• New *Page.CropBox* and *Page.MediaBox* have been included for convenience.
16.75 Changes in Version 1.12.1

This is an extension of version 1.12.0.

• New method `Page.show_pdf_page()` displays another’s PDF page. This is a vector image and therefore remains precise across zooming. Both involved documents must be PDF.

• New method `Page.getSVGimage()` creates an SVG image from the page. In contrast to the raster image of a pixmap, this is a vector image format. The return is a unicode text string, which can be saved in a .svg file.

• Method `Page.getTextBlocks()` now accepts an additional bool parameter “images”. If set to true (default is false), image blocks (metadata only) are included in the produced list and thus allow detecting areas with rendered images.

• Minor bug fixes.

• “text” result of `Page.getText()` concatenates all lines within a block using a single space character. MuPDF’s original uses “\n” instead, producing a rather ragged output.

• New properties of `Page` objects `Page.MediaBoxSize` and `Page.CropBoxPosition` provide more information about a page’s dimensions. For non-PDF files (and for most PDF files, too) these will be equal to `Page.rect.bottom_right`, resp. `Page.rect.top_left`. For example, class `Shape` makes use of them to correctly position its items.

16.76 Changes in Version 1.12.0

This version is based on and requires MuPDF v1.12.0. The new MuPDF version contains quite a number of changes – most of them around text extraction. Some of the changes impact the programmer’s API.

• `Outline.saveText()` and `Outline.saveXML()` have been deleted without replacement. You probably haven’t used them much anyway. But if you are looking for a replacement: the output of `Document.get_toc()` can easily be used to produce something equivalent.

• Class `TextSheet` does no longer exist.

• Text “spans” (one of the hierarchy levels of `TextPage`) no longer contain positioning information (i.e. no “bbox” key). Instead, spans now provide the font information for its text. This impacts our JSON output variant.

• HTML output has improved very much: it now creates valid documents which can be displayed by browsers to produce a similar view as the original document.

• There is a new output format XHTML, which provides text and images in a browser-readable format. The difference to HTML output is, that no effort is made to reproduce the original layout.

• All output formats of `Page.getText()` now support creating complete, valid documents, by wrapping them with appropriate header and trailer information. If you are interested in using the HTML output, please make sure to read ‘Controlling Quality of HTML Output’.

• To support finding text positions, we have added special methods that don’t need detours like `TextPage.extractJSON()` or `TextPage.extractXML()`: use `Page.getTextBlocks()` or resp. `Page.getTextWords()` to create lists of text blocks or resp. words, which are accompanied by their rectangles. This should be much faster than the standard text extraction methods and also avoids using additional packages for interpreting their output.

16.77 Changes in Version 1.11.2

This is an extension of v1.11.1.
• New `Page.insertFont()` creates a PDF `Font` object and returns its object number.
• New `Document.extractFont()` extracts the content of an embedded font given its object number.
• Methods `FontList(...)` items no longer contain the PDF generation number. This value never had any significance. Instead, the font file extension is included (e.g. “pfa” for a “PostScript Font for ASCII”), which is more valuable information.
• Fonts other than “simple fonts” (Type1) are now also supported.
• New options to change `Pixmap` size:
  – Method `Pixmap.shrink()` reduces the pixmap proportionally in place.
  – A new `Pixmap` copy constructor allows scaling via setting target width and height.

16.78 Changes in Version 1.11.1

This is an extension of v1.11.0.
• New class `Shape`. It facilitates and extends the creation of image shapes on PDF pages. It contains multiple methods for creating elementary shapes like lines, rectangles or circles, which can be combined into more complex ones and be given common properties like line width or colors. Combined shapes are handled as a unit and e.g. be “morphed” together. The class can accumulate multiple complex shapes and put them all in the page’s foreground or background – thus also reducing the number of updates to the page’s contents object.
• All `Page` draw methods now use the new `Shape` class.
• Text insertion methods `insertText()` and `insertTextBox()` now support morphing in addition to text rotation. They have become part of the `Shape` class and thus allow text to be freely combined with graphics.
• A new `Pixmap` constructor allows creating pixmap copies with an added alpha channel. A new method also allows directly manipulating alpha values.
• Binary algebraic operations with geometry objects (matrices, rectangles and points) now generally also support lists or tuples as the second operand. You can add a tuple \((x, y)\) of numbers to a `Point`. In this context, such sequences are called “point_like” (resp. `matrix_like`, `rect_like`).
• Geometry objects now fully support in-place operators. For example, \(p /= m\) replaces point \(p\) with \(p * 1/m\) for a number, or \(p * ~m\) for a `matrix_like` object \(m\). Similarly, if \(r\) is a rectangle, then \(r |= (3, 4)\) is the new rectangle that also includes \(fitz.Point(3, 4)\), and \(r &\ (1, 2, 3, 4)\) is its intersection with \(fitz.Rect(1, 2, 3, 4)\).

16.79 Changes in Version 1.11.0

This version is based on and requires MuPDF v1.11.
Though MuPDF has declared it as being mostly a bug fix version, one major new feature is indeed contained: support of embedded files – also called portfolios or collections. We have extended PyMuPDF functionality to embrace this up to an extent just a little beyond the `mutool` utility as follows.
• The `Document` class now support embedded files with several new methods and one new property:
  – `embfile_Info()` returns metadata information about an entry in the list of embedded files. This is more than `mutool` currently provides: it shows all the information that was used to embed the file (not just the entry’s name).
  – `embfile_Get()` retrieves the (decompressed) content of an entry into a `bytes` buffer.
– `embfile_Add(…)` inserts new content into the PDF portfolio. We (in contrast to `mutool`) restrict this to entries with a new name (no duplicate names allowed).

– `embfile_Del(…)` deletes an entry from the portfolio (function not offered in MuPDF).

– `embfile_SetInfo()` – changes filename or description of an embedded file.

– `embfile_Count` – contains the number of embedded files.

- Several enhancements deal with streamlining geometry objects. These are not connected to the new MuPDF version and most of them are also reflected in PyMuPDF v1.10.0. Among them are new properties to identify the corners of rectangles by name (e.g. `Rect.bottom_right`) and new methods to deal with set-theoretic questions like `Rect.contains(x)` or `IRect.intersects(x)`. Special effort focussed on supporting more “Pythonic” language constructs: `if x in rect …` is equivalent to `rect.contains(x)`.

- The `Rect` chapter now has more background on empty and infinite rectangles and how we handle them. The handling itself was also updated for more consistency in this area.

- We have started basic support for generation of PDF content:
  – `Document.insert_page()` adds a new page into a PDF, optionally containing some text.
  – `Page.insertImage()` places a new image on a PDF page.
  – `Page.insertText()` puts new text on an existing page.

- For `FileAttachment` annotations, content and name of the attached file can extracted and changed.

### 16.80 Changes in Version 1.10.0

#### 16.80.1 MuPDF v1.10 Impact

MuPDF version 1.10 has a significant impact on our bindings. Some of the changes also affect the API – in other words, you as a PyMuPDF user.

- Link destination information has been reduced. Several properties of the `linkDest` class no longer contain valuable information. In fact, this class as a whole has been deleted from MuPDF’s library and we in PyMuPDF only maintain it to provide compatibility to existing code.

- In an effort to minimize memory requirements, several improvements have been built into MuPDF v1.10:
  – A new `config.h` file can be used to de-select unwanted features in the C base code. Using this feature we have been able to reduce the size of our binary `_fitz.o` / `_fitz.pyd` by about 50% (from 9 MB to 4.5 MB). When UPX-ing this, the size goes even further down to a very handy 2.3 MB.
  – The alpha (transparency) channel for pixmaps is now optional. Letting alpha default to `False` significantly reduces pixmap sizes (by 20% – CMYK, 25% – RGB, 50% – GRAY). Many `Pixmap` constructors therefore now accept an `alpha` boolean to control inclusion of this channel. Other pixmap constructors (e.g. those for file and image input) create pixmaps with no alpha altogether. On the downside, save methods for pixmaps no longer accept a `savealpha` option: this channel will always be saved when present. To minimize code breaks, we have left this parameter in the call patterns – it will just be ignored.

- `DisplayList` and `TextPage` class constructors now require the `mediabox` of the page they are referring to (i.e. the `page.bound()` rectangle). There is no way to construct this information from other sources, therefore a source code change cannot be avoided in these cases. We assume however, that not many users are actually employing these rather low level classes explicily. So the impact of that change should be minor.
16.80.2 Other Changes compared to Version 1.9.3

- The new `Document` method `write()` writes an opened PDF to memory (as opposed to a file, like `save()` does).
- An annotation can now be scaled and moved around on its page. This is done by modifying its rectangle.
- Annotations can now be deleted. `Page` contains the new method `deleteAnnot()`.
- Various annotation attributes can now be modified, e.g. content, dates, title (= author), border, colors.
- Method `Document.insert_pdf()` now also copies annotations of source pages.
- The `Pages` class has been deleted. As documents can now be accessed with page numbers as indices (like `doc[n] = doc.loadPage(n)`), and document object can be used as iterators, the benefit of this class was too low to maintain it. See the following comments.
- `loadPage(n) / doc[n]` now accept arbitrary integers to specify a page number, as long as `n < pageCount`. So, e.g. `doc[-500]` is always valid and will load page `(-500) % pageCount`.
- A document can now also be used as an iterator like this: `for page in doc: ... <do something with “page”> ...`. This will yield all pages of `doc` as `page`.
- The `Pixmap` method `getSize()` has been replaced with property `size`. As before `Pixmap.size == len(Pixmap)` is true.
- In response to transparency (alpha) being optional, several new parameters and properties have been added to `Pixmap` and `Colorspace` classes to support determining their characteristics.
- The `Page` class now contains new properties `firstAnnot` and `firstLink` to provide starting points to the respective class chains, where `firstLink` is just a mnemonic synonym to method `loadLinks()` which continues to exist. Similarly, the new property `rect` is a synonym for method `bound()`, which also continues to exist.
- `Pixmap` methods `samplesRGB()` and `samplesAlpha()` have been deleted because pixmaps can now be created without transparency.
- `Rect` now has a property `irect` which is a synonym of method `round()`. Likewise, `IRect` now has property `rect` to deliver a `Rect` which has the same coordinates as floats values.
- Document has the new method `searchPageFor()` to search for a text string. It works exactly like the corresponding `Page.searchFor()` with page number as additional parameter.

16.81 Changes in Version 1.9.3

This version is also based on MuPDF v1.9a. Changes compared to version 1.9.2:

- As a major enhancement, annotations are now supported in a similar way as links. Annotations can be displayed (as pixmaps) and their properties can be accessed.
- In addition to the document `select()` method, some simpler methods can now be used to manipulate a PDF:
  - `copyPage()` copies a page within a document.
  - `movePage()` is similar, but deletes the original.
  - `delete_page()` deletes a page
  - `delete_pages()` deletes a page range
- `rotation` or `setRotation()` access or change a PDF page’s rotation, respectively.
- Available but undocumented before, `IRect`, `Rect`, `Point` and `Matrix` support the `len()` method and their coordinate properties can be accessed via indices, e.g. `IRect.x1 == IRect[2]`. 

16.81. Changes in Version 1.9.3 327
• For convenience, documents now support simple indexing: `doc.loadPage(n) == doc[n]`. The index may how-
however be in range `-pageCount < n < pageCount`, such that `doc[-1]` is the last page of the document.

16.82 Changes in Version 1.9.2

This version is also based on MuPDF v1.9a. Changes compared to version 1.9.1:

• `fitz.open()` (no parameters) creates a new empty PDF document, i.e. if saved afterwards, it must be given a .pdf extension.

• `Document` now accepts all of the following formats (Document and open are synonyms):
  
  – `open()`,
  
  – `open(filename)` (equivalent to `open(filename, None)`),
  
  – `open(filetype, area)` (equivalent to `open(filetype, stream = area)`).

Type of memory area `stream` may be `bytes` or `bytearray`. Thus, e.g. `area = open("file.pdf", "rb").read()` may be used directly (without first converting it to bytearray).

• New method `Document.insert_pdf()` (PDFs only) inserts a range of pages from another PDF.

• `Document` objects doc now support the `len()` function: `len(doc) == doc.pageCount`.

• New method `Document.getPageImageList()` creates a list of images used on a page.

• New method `Document.getPageFontList()` creates a list of fonts referenced by a page.

• New pixmap constructor `fitz.Pixmap(doc, xref)` creates a pixmap based on an opened PDF document and an `xref` number of the image.

• New pixmap constructor `fitz.Pixmap(cspace, spix)` creates a pixmap as a copy of another one `spix` with the colorspace converted to `cspace`. This works for all colorspace combinations.

• Pixmap constructor `fitz.Pixmap(colorsace, width, height, samples)` now allows `samples` to also be `bytes`, not only `bytearray`.

16.83 Changes in Version 1.9.1

This version of PyMuPDF is based on MuPDF library source code version 1.9a published on April 21, 2016.

Please have a look at MuPDF’s website to see which changes and enhancements are contained herein.

Changes in version 1.9.1 compared to version 1.8.0 are the following:

• New methods `getRectArea()` for both `fitz.Rect` and `fitz.IRect`.

• Pixmaps can now be created directly from files using the new constructor `fitz.Pixmap(filename)`.

• The Pixmap constructor `fitz.Pixmap(image)` has been extended accordingly.

• `fitz.Rect` can now be created with all possible combinations of points and coordinates.

• PyMuPDF classes and methods now all contain __doc__ strings, most of them created by SWIG automatically. While the PyMuPDF documentation certainly is more detailed, this feature should help a lot when programming in Python-aware IDEs.

• A new document method of `getPermits()` returns the permissions associated with the current access to the document (print, edit, annotate, copy), as a Python dictionary.

• The identity matrix `fitz.Identity` is now immutable.
• The new document method `select(list)` removes all pages from a document that are not contained in the list. Pages can also be duplicated and re-arranged.

• Various improvements and new members in our demo and examples collections. Perhaps most prominently: `PDF_display` now supports scrolling with the mouse wheel, and there is a new example program `wxTableExtract` which allows to graphically identify and extract table data in documents.

• `fitz.open()` is now an alias of `fitz.Document()`.

• New pixmap method `getPNGData()` which will return a bytearray formatted as a PNG image of the pixmap.

• New pixmap method `samplesRGB()` providing a `samples` version with alpha bytes stripped off (RGB colorspace only).

• New pixmap method `samplesAlpha()` providing the alpha bytes only of the `samples` area.

• New iterator `fitz.Pages(doc)` over a document’s set of pages.

• New matrix methods `invert()` (calculate inverted matrix), `concat()` (calculate matrix product), `preTranslate()` (perform a shift operation).

• New `IRect` methods `intersect()` (intersection with another rectangle), `translate()` (perform a shift operation).

• New `Rect` methods `intersect()` (intersection with another rectangle), `transform()` (transformation with a matrix), `includePoint()` (enlarge rectangle to also contain a point), `includeRect()` (enlarge rectangle to also contain another one).

• Documented `Point.transform()` (transform a point with a matrix).

• `Matrix`, `IRect`, `Rect` and `Point` classes now support compact, algebraic formulations for manipulating such objects.

• Incremental saves for changes are possible now using the call pattern `doc.save(doc.name, incremental=True)`.

• A PDF’s metadata can now be deleted, set or changed by document method `set_metadata()`. Supports incremental saves.

• A PDF’s bookmarks (or table of contents) can now be deleted, set or changed with the entries of a list using document method `set_toc(list)`. Supports incremental saves.
This list maps deprecated names of methods and attributes to their new “snake_case” versions.

This is a major effort, that we only can muster in a step-wise fashion. We believe, we so far (v1.18.7) are done with `Annot`, `Document`, `Page`, `Shape` and `TextWriter`.

Names of classes (camel case) and package-wide constants (the majority is upper case) remain untouched. Deprecated names will remain available through MuPDF version 1.19.0 and probably be removed in v1.20.0.

Deprecated names will no longer be separately documented.

Note: The following list is automatically generated.

- References to new names (right column) always refer to method names - even if the name actually is a property. Please lookup to disambiguate.
- One or two items refer to yet undocumented methods - please simply ignore.
